DISCRIMINANT METHOD FOR THE HOMOLOGICAL MONODROMY OF TAME POLYNOMIALS.

MARIO ESCARIO GIL

Abstract. We construct an effective algorithmic method to compute the homological monodromy of a complex polynomial which is tame. As an application we show the existence of conjugated polynomials in a number field which are not topologically equivalent.

1. Introduction

Let $f : \mathbb{C}^n \to \mathbb{C}$ be a polynomial function. It induces a locally trivial fibration over $\mathbb{C} \setminus B_f$ with B_f the minimal finite bifurcation set; this is a consequence of Thom's work [28] and a proof can be found in [25, Appendix A1] or [29, Corollary 5.1]. Let T be a big disk so that $B_f \subset \operatorname{Int}(T)$ and $\star \in \partial T$. A classical construction gives us a geometric basis (γ_i) of $\pi_1(T \setminus B_f; \star)$ (see Definition 2.2) and this basis provides a direct sum decomposition of $\tilde{H}_q(f^{-1}(\star))$ (reduced homology over $\mathbb{Z}$) which depends essentially on the choice of (γ_i) (see [9, 12, 13, 23, 24, 26] for varius degrees of generality). With this sum decomposition and if f has only isolated singularities, local monodromy $(h_{\gamma_i})_*$ has a block decomposition. There are two kinds of blocks: *local blocks* which only depend on the local Milnor fibers and *global blocks* which depend on the embedings of the local Milnor fibers into the fixed regular fiber $f^{-1}(\star)$. There are several papers dealing with the local blocks and how to compute them, for example, Brieskorn singularities by A. Hefez and F. Lazzari [21], certain singularities and unimodal singularities by A. M. Gabriélov [15, 16] and general methods like the one which uses real morsifications due to N. A'Campo [1, 2] and S. M. Gusein-Zade [19, 20] and the one which uses an inductive argument due to A. M. Gabriélov [17]. This is not the situation for the global blocks. There are some relations between local and global blocks (see W. Neumann and P. Norbury [23, Theorem 3.3]) which can give useful constraints but, nevertheless, usually these data are computed depending on the particular polynomial f and a practical complete algorithmic method does not exist in the literature.

Specially interesting is the case of conjugated polynomials in a number field, i.e., a polynomial with coefficients in a number field and its image by a Galois isomorphism of the field. Due to the Galois isomorphism both have the same algebraic properties (degree, number of components, global Milnor number, Alexander polynomials, types and position of singularities, ...). In order to topologically distinguish these polynomials it seems a good idea to compute the global blocks, since they reflect how the Milnor fibers sit in the fixed regular fiber and this need not be invariant under Galois isomorphims.

We have constructed a practical complete algorithmic method to compute local monodromies for a tame polynomial f with $n = 2$ (see S. A. Broughton [9, Definition 3.1]). This implies that there exist morsifications $\tilde{f}$ of f whose regular fibers

are diffeomorphic, and $B_f = \{t_i\}$ contains only critical values coming from affine singularities. This way we can compute the local monodromies of f from the local monodromies of $\tilde{f}$. To obtain the block decomposition of the local monodromies $(h_{\gamma_i})_*$ we need to consider *special geometric bases* of $\pi_1(T \setminus B_{\tilde{f}}; \star)$ associated with (γ_i). We can construct this basis as follows. Let $(t_i, \star_i, r_i, S_i, D_i)$ be the elements associated with γ_i (see Figure 1). For a sufficiently small deformation $\tilde{f}$, $B_{\tilde{f}} \cap D_i$ is

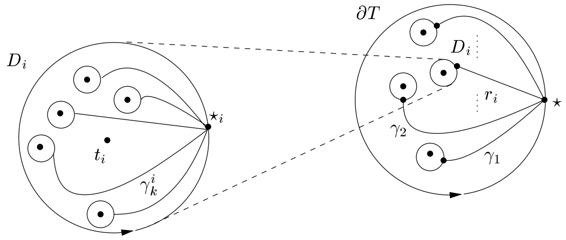

Figure 1.

the set of those critical values which belong to the morsification of the singularities in $f^{-1}(t_i)$. We order the set $B_{\tilde{f}} \cap D_i$ in such a way that the critical values corresponding to the morsification of the same critical point in $f^{-1}(t_i)$ are together. We can consider a geometric basis $(\gamma^i_k)_{k=1,\dots,k(i)}$ of $\pi_1(D_i \setminus B_{\tilde{f}} \cap D_i; \star_i)$ which respects this order so that $(r_i \cdot \gamma^i_k \cdot r_i^{-1})^{i=1,\dots,\#B_f}_{k=1,\dots,k(i)}$ is a geometric basis of $\pi_1(T \setminus B_{\tilde{f}}; \star)$. Note that, for a fixed i, the path $r_i \cdot (\prod_k \gamma^i_k) \cdot r_i^{-1}$ is homotopic to γ_i and hence the ordered product of the associated local monodromies gives the block decomposition of $(h_{\gamma_i})_*$ (see Remark 5.6). Moreover, the ordered product of the $(h_{\gamma_i})_*$ produces the monodromy at infinity.

We will then construct a method to compute the local monodromies for a tame Morse function. Hence we can assume f to be this tame Morse function. Let $\mathfrak{D}_f := \{(t,x) \in \mathbb{C}^2 \mid \operatorname{discrim}_y(f(x,y)-t) = 0\}$ be the curve discriminant of the polar mapping $\phi_{f,x} : \mathbb{C}^2 \to \mathbb{C}^2, (x,y) \mapsto (t,x) := (f(x,y),x)$. The method needs two data which depend on $\mathfrak{D}_f$. The first one is the classical monodromy m of the projection $\pi| : f^{-1}(\star) \to \mathbb{C}, (x,y) \mapsto x$, in particular we need to know the transpositions given by a geometric basis (μ_n) associated with the ramification points of $\pi|_{f^{-1}(\star)}$ (the set of k points given by $\mathfrak{D}_f \cap \{t = \star\}$). The second ingredient is the braid monodromy ∇ of the projection $\pi| : \mathfrak{D}_f \to \mathbb{C}, (t,x) \mapsto t$, in particular we need to know the braids determined by the geometric basis (γ_i). The computation of these data can be done with the help of computer programs such as [6] and [10]. Since our method uses strongly the discriminant curve $\mathfrak{D}_f$ we call it *the discriminant method*.

In the following we sketch our method. Let $\mathbb{F}_k$ be the free group of k generators: $\mu_1, \dots, \mu_k$ and let $\mathbb{B}_k$ be the braid group on k strings given by the following representation

$$\langle \sigma_1, \dots, \sigma_{k-1} \mid [\sigma_i, \sigma_j] = 1 \text{ if } |i-j| \geq 2, \sigma_{i+1}\sigma_i\sigma_{i+1} = \sigma_i\sigma_{i+1}\sigma_i, i = 1, \dots, k-2\rangle .$$

Since f is a Morse polynomial, the braid $\nabla(\gamma_i)$ can be written as a conjugate of any basis element σ_j. Let β_i be the element which conjugates, for example, σ_1 (this can be obtained from the braid monodromy calculated above). There is a natural right action $\Phi : \mathbb{F}_k \times \mathbb{B}_k \to \mathbb{F}_k$ such that

$$\mu_j^{\sigma_i} = \begin{cases} \mu_{i+1} & \text{if } j = i \\ \mu_{i+1} \cdot \mu_i \cdot \mu_{i+1}^{-1} & \text{if } j = i+1 \\ \mu_j & \text{if } j \neq i, i+1, \end{cases}$$

in exponential notation. We compute the elements $\mu_1^{\beta_i}$ and $\mu_2^{\beta_i}$ and denote by δ_i their product. Note that δ_i (resp. $\delta_i^{\nabla(\gamma_j)}$) is the image by $\pi|_{f^{-1}(\star)}$ of a path in $f^{-1}(\star)$ defining a vanishing 1-cycle Δ_i (resp. the Picard-Lefschetz element $(h_{\gamma_j})_*(\Delta_i)$). We construct an appropriate model of the fiber $f^{-1}(\star)$ that enables us to perform algebraic computations. This model allows us to express the 1-homology of the fiber $f^{-1}(\star)$ in terms of the generators (μ_n) via the classical monodromy calculated above. Finally using the expression of δ_i and $\delta_i^{\nabla(\gamma_j)}$ in the basis (μ_n) and by means of the 1-homology model we can express the cycles Δ_i and $(h_{\gamma_i})_*(\Delta_j)$ algebraically.

We develop the discriminant method in Section 4. In Section 4.1 we construct the aforementioned model of the fiber $f^{-1}(\star)$. Afterwards, in Section 4.2 we explain the method in the Morse function case and state the main Theorem 4.10 on their local monodromy. Finally in Section 4.3 we apply the method using generic morsifications for the tame case. Sections 3 and 6 are mainly technical in order to prove the main theorem and its application to tame polynomials.

In Section 5 we prove the existence of non-topologically equivalent tame polynomials whose equations are conjugated in the number field $\mathbb{Q}(\sqrt{3})$ (we thank E. Artal and A. Bodin for suggesting these polynomials as worth studying). To do this we prove that under certain conditions, if two polynomials are topologically equivalent then their local monodromies should be simultaneously conjugated by the same invertible matrix. Using the discriminant method we completly compute local and global blocks in a distinguished basis of vanishing cycles and we show that such simultaneous conjugation does not exist.

Finally Section 2 is devoted to setting definitions, notations and properties of geometric bases, braids and Hurwitz moves.

Acknoledgement. We deeply appreciate the support and valuable ideas suggested by E. Artal and J.I. Cogolludo.

2. Geometric bases, braids and Hurwitz moves

All results and definitions in this section can be found, more extensively, in [5] and [7]. Notations follow [4].

Definition 2.1. Let $S \subset \mathbb{C}$ be a finite set of points and $t_o \in \mathbb{C} \setminus S$. We say the path φ is a *meridian in* $\mathbb{C} \setminus S$ *of the point* $t_\varphi \in S$ *and based at* t_o (Figure 2) if φ is the union of paths $r_\varphi \cdot S_\varphi \cdot r_\varphi^{-1}$ with S_φ the positive oriented boundary of a disk D_φ with center t_φ such that $D_\varphi \cap S = \{t_\varphi\}$ and r_φ path from t_o to $t'_\varphi \in S_\varphi$ such that $\mathrm{Supp}(r_\varphi) \cap S = \emptyset$. If r_φ has not self intersections φ is said *simple*.

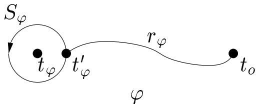

Figure 2.

Let $\Omega \subset \mathbb{C}$ be a simple compact region, $S \subset \mathrm{Int}(\Omega)$ set with s points and $t_o \in \partial\Omega$. We consider special families of bases in the fundamental group $\pi_1(\Omega \setminus S; t_o)$.

Definition 2.2. A *geometric basis* of the group $\pi_1(\Omega \setminus S; t_o)$ is an ordered list $(\varphi_1, \dots, \varphi_s)$ such that:

(i) φ_i is a simple meridian in $\Omega \setminus S$ based at t_o defined by $(t_{\varphi_i}, t'_{\varphi_i}, r_{\varphi_i}, S_{\varphi_i}, D_{\varphi_i})$.
(ii) $\mathrm{Supp}(\varphi_i) \cap \mathrm{Supp}(\varphi_j) = \{t_o\}$ for all i, j with $i \neq j$.

(iii) $\varphi_s \cdot \ldots \cdot \varphi_1$ is homotopic to $\partial\Omega$ which is positively oriented (product from left to right).

Example 2.3. Let X be a geometric disk centered at $0 \in \mathbb{C}$ such that $\{1, 2, \ldots, k\} \subset \mathrm{Int}(X)$. Let $* \in \partial X \cap \mathbb{R}^+$. Figure 3 shows a list of meridians $(\mu_1, \ldots, \mu_k)$ defining a geometric basis of $\pi_1(X \setminus \{1, 2, \ldots, k\}; *)$. ■

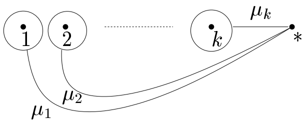

FIGURE 3.

Definition 2.4. Let $\mathcal{V}$ be the topological space of sets with k different points in $\mathbb{C}$. We write $\mathbb{B}(\mathbf{s}^1, \mathbf{s}^2), \mathbf{s}^1, \mathbf{s}^2 \in \mathcal{V}$, the set of braids which start at $\mathbf{s}^1$ and end at $\mathbf{s}^2$. As it is usual we denote simply by $\mathbb{B}_k$ the group $\mathbb{B}(\{1, \ldots, k\}, \{1, \ldots, k\})$.

Proposition 2.5. *The group $\mathbb{B}_k$ is generated by elements $\sigma_j, j = 1, \ldots, k-1$ (Figure 4) with relations $[\sigma_i, \sigma_j] = 1$ if $|i - j| \geq 2$ and $\sigma_{i+1}\sigma_i\sigma_{i+1} = \sigma_i\sigma_{i+1}\sigma_i$, $i = 1, \ldots, k-2$.*

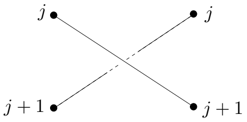

FIGURE 4. Braid σ_j.

Definition 2.6. A *base set of braids* $\mathfrak{D}$ is a set such that for every $\mathbf{s} \in \mathcal{V}$ there exists a unique braid $\tau_{\mathbf{s},\mathfrak{D}} \in \mathfrak{D}$ with $\tau_{\mathbf{s},\mathfrak{D}} \in \mathbb{B}(\{1, \ldots, k\}, \mathbf{s})$.

Notation 2.7. Let $\psi \in (0, \pi)$.

- Define by $\pi_\psi(z) := \Re(z) - (\Im(z)/\tan(\psi))$ a certain projection of $\mathbb{C}$ onto $\mathbb{R}$. Let the lexicographic order $<^\psi$ in $\mathbb{C}$ (Figure 5) given by
$$z <^\psi w \iff \pi_\psi(z) < \pi_\psi(w) \quad \text{or } \pi_\psi(z) = \pi_\psi(w) \text{ and } \Im(z) < \Im(w).$$

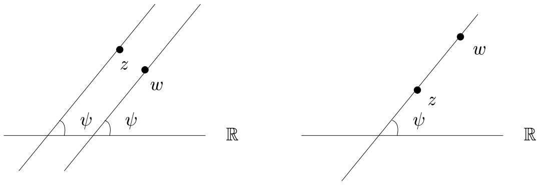

FIGURE 5. The two cases $z <^\psi w$.

- For $\mathbf{s} \in \mathcal{V}$ we consider the k-tuple $\mathbf{s}(\psi) := (s_1, \ldots, s_k), s_i \in \mathbf{s}$, such that it verifies $s_1 <^\psi s_2 <^\psi \ldots <^\psi s_k$.
- We denote by $\mathcal{V}(\psi)$ the set of lists $\mathbf{s}(\psi), \mathbf{s} \in \mathcal{V}$.
- We denote by $\mathfrak{D}(\psi)$ a base set of braids such that every $\tau_{\mathbf{s},\mathfrak{D}(\psi)}$ has a set of strands $\{\alpha_1, \ldots, \alpha_k\}$ with $(\alpha_1(u), \ldots, \alpha_k(u)) \in \mathcal{V}(\psi), \forall u \in [0, 1]$, and $\alpha_i(0) = i$, $\alpha_i(1) = s_i$. For instance $\alpha_i(u) = s_i \cdot u + i \cdot (1 - u), i = 1, \ldots, k$.

Let $\mathbf{s}^1, \mathbf{s}^2 \in \mathcal{V}$ and $\mathfrak{D}$ a base set of braids. One can define the bijection

$$\mathbb{B}(\mathbf{s}^1, \mathbf{s}^2) \xrightarrow{\mathbb{I}_{\mathbf{s}^1,\mathbf{s}^2,\mathfrak{D}}} \mathbb{B}_k,\ \tau \mapsto \tau_{\mathbf{s}^1,\mathfrak{D}}\, \tau\, \tau^{-1}_{\mathbf{s}^2,\mathfrak{D}} =: \tau(\mathfrak{D}) \tag{2.1}$$

Proposition 2.8.

(a) $\mathbb{I}_{\bullet,\bullet,\mathfrak{D}}$ *is an isomorphism of grupoïds.*

(b) Let $\mathfrak{D}$ *and* $\bar{\mathfrak{D}}$ *base sets of braids and* $\tau \in \mathbb{B}(\mathbf{s}^1, \mathbf{s}^2)$ *then*

$$\tau(\bar{\mathfrak{D}}) = (\tau_{\mathbf{s}^1,\bar{\mathfrak{D}}}\, \tau^{-1}_{\mathbf{s}^1,\mathfrak{D}})\, \tau(\mathfrak{D})\, (\tau_{\mathbf{s}^2,\bar{\mathfrak{D}}}\, \tau^{-1}_{\mathbf{s}^2,\mathfrak{D}})^{-1}.$$

In fact if $\mathbf{s^1} = \mathbf{s^2}$*, braids* $\tau(\mathfrak{D})$ *and* $\tau(\bar{\mathfrak{D}})$ *are conjugated in* $\mathbb{B}_k$*.*

Let $\tau \in \mathbb{B}(\mathbf{s}^1, \mathbf{s}^2)$, X a disk such that $\mathbf{s}^1 \cup \mathbf{s}^2 \subset \operatorname{Int}(X)$ and $* \in \partial X$.

Definition 2.9. A map $H : \mathbb{C}\times[0,1] \to \mathbb{C}$ is said a $(\mathbf{s}^1, \mathbf{s}^2)$-*special isotopy associated with* τ if $H(\bullet, u)$, u fix, is a preserving orientation homomorphism so that is the identity in $\mathbb{C} \setminus \operatorname{Int}(X)$ and $H|_{\mathbf{s}^1\times[0,1]}$ defines the braid τ.

Definition 2.10. We define the *Hurwitz move associated with* τ as the isomorphism

$$\Psi_\tau : \pi_1(X \setminus \mathbf{s}^1; *) \to \pi_1(X \setminus \mathbf{s}^2; *), \varrho \mapsto \Psi_\tau(\varrho) =: \varrho^\tau$$

which defines a $(\mathbf{s}^1, \mathbf{s}^2)$-special isotopy associated with τ and we denote by

$$\Phi_{\mathbf{s}^1,\mathbf{s}^2} : \pi_1(X \setminus \mathbf{s}^1; *) \times \mathbb{B}(\mathbf{s}^1, \mathbf{s}^2) \to \pi_1(X \setminus \mathbf{s}^2; *)$$

the right grupoïd action defined by Hurwitz moves.

Example 2.11. Let us consider the situation given in Example 2.3. The action $\Phi_{\mathbf{x},\mathbf{x}}$ is defined by

$$\mu_j^{\sigma_i} = \begin{cases} \mu_{i+1} & \text{if } j = i \\ \mu_{i+1}\ \cdot\ \mu_i\ \cdot \mu_{i+1}^{-1} & \text{if } j = i+1 \\ \mu_j & \text{if } j \neq i, i+1. \end{cases} \tag{2.2}$$

Also note that for any base set of braids $\mathfrak{D}$ we have the commutative diagram

$$\begin{tikzcd} \pi_1(X \setminus \mathbf{s}^1; *) \times \mathbb{B}(\mathbf{s}^1, \mathbf{s}^2) \arrow[r, "\Phi_{\mathbf{s}^1,\mathbf{s}^2}"] \arrow[d, "\Psi^{-1}_{\tau_{\mathbf{s}^1,\mathfrak{D}}}\times\mathbb{I}_{\mathbf{s}^1,\mathbf{s}^2,\mathfrak{D}}"'] \arrow[dr, phantom, "\circlearrowleft"] & \pi_1(X \setminus \mathbf{s}^2; *) \\ \pi_1(X \setminus \{1, \ldots, k\}; *) \times \mathbb{B}_k \arrow[r, "\Phi_{\mathbf{x},\mathbf{x}}"] & \pi_1(X \setminus \{1, \ldots, k\}; *) \arrow[u, "\Psi_{\tau_{\mathbf{s}^2,\mathfrak{D}}}"'] \end{tikzcd} \tag{2.3}$$

■

From Proposition 2.5 and action (2.2) we have the following lemma.

Lemma 2.12. *Let* $\alpha_s := (\sigma_2\sigma_1)(\sigma_3\sigma_2)\ldots(\sigma_s\sigma_{s-1}) \in \mathbb{B}_k, s = 2, \ldots, k-1$*. Then:*

(a) $\sigma_s = \alpha_s^{-1}\sigma_1\alpha_s$*.*

(b) $\mu_s = \mu_1^{\alpha_s}$ *and* $\mu_{s+1} = \mu_2^{\alpha_s}$*.*

3. Discriminant properties

Let $f \in \mathbb{C}[x, y]$ be a monic polynomial of degree N in the variable y with isolated singularities. Let

$$\phi_{f,l} : \mathbb{C}^2 \longrightarrow \mathbb{C}^2,\ (x, y) \mapsto (f(x, y), l(x, y))$$

the polar map associated with f. We take the linear form $l(x, y) = x$. In this case the discriminant curve $\mathfrak{D}_f$ of $\phi_{f,x}$ (i.e., the image of the critical locus of $\phi_{f,x}$) has the equation

$$d_f(t, x) := \operatorname{discrim}_y(f(x, y) - t) \in \mathbb{C}[t, x].$$

Notation 3.1. We denote by μ_{t_o,x_o} the sum of Milnor numbers of the singularities in $f^{-1}(t_o)$ whose projection onto the first variable x is $x_o \in \mathbb{C}$.

Lemma 3.2. *Let r be the number of different roots of $f(0,y)$. Then the discriminant $d_f(t,x)$ is x-regular of degree $\mu_{0,0}+N-r$ and t-regular of degree $N-r$.*

Proof. Let $y_j \in \mathbb{C}, j=1,\dots,r$, root of $f(0,y)$ with multiplicity N_j. By Hensel's Lemma [18, page 44] we write $f(x,y)=\prod_{j=1}^{r} P_j(x,y), x \in \mathbb{D}$, with $\mathbb{D}$ small disk centered at $0 \in \mathbb{C}$ and $P_j(x,y)$ Weierstrass polynomial centered at $(0,y_j)$ of degree N_j in the variable y. As $f^{-1}(0)$ has isolated singularities then P_j is reduced and so $\mathrm{discrim}_y(P_j)$ is not zero and we deduce that t does not divide $\mathrm{discrim}_y(P_j-t)$. Then $\mathrm{discrim}_y(P_j-t)$ is x-regular of degree [27, page 317]

$$\mu(P_j)+N_j-1. \tag{3.1}$$

By properties of the resultant we have

$$\mathrm{discrim}_y(P_iP_j) = (\mathrm{result}_y(P_i,P_j))^2\,\mathrm{discrim}_y(P_i)\,\mathrm{discrim}_y(P_j)$$

where $\mathrm{result}_y(P_i,P_j) \in \mathbb{C}\{x\}$ is a unit because P_i and P_j do not share their Puiseux series. Then we deduce that the degree of $d_f(0,x)$ is the sum of the degrees of $\mathrm{discrim}_y(P_j), j=1,\dots,r$, and finally by (3.1) $d_f(t,x)$ is x-regular of degree

$$\sum_{j=1}^{r}(\mu(P_j)+N_j-1)=\mu_{0,0}+N-r.$$

For the second part of the lemma we note that $f(0,y)$ and $f'(0,y)$ share y_j as root of multiplicity N_j-1. Then $d_f(t,0)$ has 0 as a root of multiplicity $\sum_{j=1}^{r}(N_j-1)=N-r$. Then $d_f(t,x)$ is t-regular of degree $N-r$. □

Corollary 3.3. *Under the notation of Lemma 3.2 the germ $(\mathfrak{D}_f,0)$ is empty if and only if $N=r$, it is smooth if and only if $N=r+1$ and it is singular if and only if $N>r+1$. Moreover, in the case $N \geq r+1$ the line $\{t=0\}$ belongs to its tangent cone if and only if $\mu_{0,0}>0$.*

Corollary 3.4. *The point $0 \in \mathbb{C}$ is a critical value of f if and only if $\{t=0\}$ belongs to the tangent cone of $\mathfrak{D}_f$.*

Proof. The point $(p_x,p_y) \in f^{-1}(0)$ is a critical point if and only if $\mu_{0,p_x}>0$ and by Corollary 3.3 (at the point $(0,p_x)$ by change of variable) if and only if $\{t=0\}$ belongs to the tangent cone of $\mathfrak{D}_f$. □

Corollary 3.5. *Let assume that the line $\{t=0\}$ is tangent at only one point p of $\mathfrak{D}_f$. If p is smooth and $(\mathfrak{D}_f,\{t=0\})_p=2$ then $f^{-1}(0)$ only has one singular point which is no degenerate.*

Proof. Without loss of generality we can suppose that $p=0 \in \mathbb{C}^2$. As multiplicity of $\{t=0\}$ in $\mathfrak{D}_f$ is 2 then $d_f(t,x)$ is x-regular of degree 2. Also as $0 \in \mathfrak{D}_f$ is a smooth no inflection point by Corollary 3.3 we have $N=r+1$ then by Lemma 3.2 we have $\mu_{0,0}+N-r=2$ so $\mu_{0,0}=1$. Then there is only one no degenerate singular point in $f^{-1}(0)$ with projection onto the first variable $0 \in \mathbb{C}$. Finally, by Corollary 3.3, there is not other singular point in $f^{-1}(0)$ because $\{t=0\}$ is only tangent at $0 \in \mathfrak{D}_f$. □

Lemma 3.6. *Let us denote by $f_\lambda(x,y) := f(x+\lambda y, y)$. For almost every $\lambda \in \mathbb{C}$ the discriminant $\mathfrak{D}_{f_\lambda}$ is a reduced curve in $\mathbb{D}\times\mathbb{C}$ with $\mathbb{D}$ small disk centered at $0 \in \mathbb{C}$.*

Proof. The polynomials $f_\lambda(x,y)$ have only isolated singularities in the zero fiber for every $\lambda \in \mathbb{C}$. We consider $d_{f_\lambda}(t,x) \in \mathbb{C}[t,x,\lambda]$ as a polynomial in the variable x. By Lemma 3.2 this polynomial is not zero for any $(t,\lambda) \in \mathbb{D}\times\mathbb{C}$ with $\mathbb{D}$ small disk centered at $0 \in \mathbb{C}$. We reduce $\mathbb{D}$ if necessary such that $f^{-1}(t')$ is smooth for every $t' \in \mathbb{D} \setminus \{0\}$. We consider $\operatorname{discrim}_x(d_{f_\lambda}(t,x)) \in \mathbb{C}[t,\lambda]$ as a polynomial in the variable λ. If this polynomial is not zero in $\mathbb{D}$ then $\lambda_o \in \mathbb{C}$ is a root (for every $t \in \mathbb{D}$) if and only if the polynomial $d_{f_{\lambda_o}}(t,x)$ is not reduced. Then for $\lambda \neq \lambda_o$ the discriminant $\mathfrak{D}_{f_\lambda}$ is reduced in $\mathbb{D} \times \mathbb{C}$. Therefore lemma will be proved if it exists a point $t_o \in \mathbb{D} \setminus \{0\}$ such that $\operatorname{discrim}_x(d_{f_\lambda}(t_o,x))$ is not zero.

Let F_{λ,t_o} homogeneous polynomial associated with $f_\lambda - t_o, t_o \in \mathbb{D} \setminus \{0\}$. The projective curve $\mathcal{Z}(F_{\lambda,t_o})$ is smooth except for maybe at a finite number of points on the line at infinity $\{z=0\}$. We can decompose $\mathcal{Z}(F_{0,t_o}) = \mathcal{L} \cup \mathcal{C}$ where $\mathcal{L}$ is the line components in $\mathcal{Z}(F_{0,t_o})$. The projective curve $\mathcal{C}$ (without lines as components) has a finite number $\mathcal{L}'$ of tangent lines at inflection points and bitangent at smooth points (see, for example, [8, Theorem 1, Section 7.3]). Let $\{a_i x + b_i y + c_i z = 0\}$ the union $\mathcal{L}' \cup \mathcal{L}$. Then only the lines $\{a_i(x+\lambda y) + b_i y + c_i z = 0\}$ are tangent lines at inflection points or bitangent at smooth points of $\mathcal{Z}(F_{\lambda,t_o})$ for every $\lambda \in \mathbb{C}$. Let $\lambda \neq -\frac{b_i}{a_i}$. The lines $\{ax + cz = 0\}$ are not tangent lines at inflection points or bitangent at smooth points of $\mathcal{Z}(F_{\lambda,t_o})$, so the line $\{ax + c = 0\}$ cut to the affine curve $f_\lambda^{-1}(t_o)$ in a traversal way or it is tangent at only one smooth no inflection point. Then the projection of $f_\lambda^{-1}(t_o)$ onto the variable x has as ramification points $x_o \in \mathbb{C}$ such as the line $\{x = x_o\}$ is tangent at only one smooth point of $f_\lambda^{-1}(t_o)$ and so $d_{f_\lambda}(t_o,x)$ is reduced and $\operatorname{discrim}_x(d_{f_\lambda}(t_o,x)) \neq 0$. □

4. Discriminant method

Let f be as at the beginning of Section 3. Let P be the set of isolated singularities of f. We fix T a geometric disk in $\mathbb{C}$ such that $f(P) \subset \operatorname{Int}(T)$ and $M := X \times Y$ a 2-dimensional polydisk with X and Y geometric disks such as:

(1) $P \subset \operatorname{Int}(X) \times \operatorname{Int}(Y)$ and $\partial M \cap f^{-1}(T) \subset \partial X \times \operatorname{Int}(Y)$.

(2) For every $t \in T$ the projection

$$\pi|_{V_t(f)} : V_t(f) \longrightarrow X,\ (x,y) \mapsto x, \tag{4.1}$$

with $V_t(f) := f^{-1}(t) \cap M$, is a covering map with N sheets and ramification points $\mathbf{x}^t := \{x_1^t, \dots, x_{k(t)}^t\} \subset \operatorname{Int}(X), k(t) \in \mathbb{N}$.

(3) $\mathbf{x} := \{1, \dots, k\} \subset \operatorname{Int}(X)$ where k is the degree of the projection

$$\pi|_{\mathfrak{D}_f} : \mathfrak{D}_f \longrightarrow T,\ (t,x) \mapsto t, \tag{4.2}$$

ramified in a set $\mathcal{T}$ (note that $k(t) = k$ if $t \in T \setminus \mathcal{T}$).

Note 4.1. We are interested in the discriminant curve in $T \times X$ then as (4.1) has its ramification points in $\operatorname{Int}(X)$, we write $\mathfrak{D}_f$ as $\mathfrak{D}_f \cap (T \times X)$. Also $\mathbf{x} \subset \operatorname{Int}(X)$ is a technical hypothesis due to taking $\mathbb{B}_k$ as our base group of braids.

By Corollary 3.4 the projection of the set of points in $\mathfrak{D}_f$ with vertical tangent line is $f(P)$ then $f(P) \subset \mathcal{T}$. Finally by Note 4.1 $\mathfrak{D}_f$ has no vertical asymptotes so $\mathcal{T} = f(P) \cup \mathcal{T}_{Sing}$ with $\mathcal{T}_{Sing}$ projection onto the first variable of $\operatorname{Sing}(\mathfrak{D}_f)$.

Let $t \in T \setminus \mathcal{T}$. Associated with (4.2) we can define the action

$$(\bar{\pi}|_{\mathfrak{D}_f})_* : \pi_1(T \setminus \mathcal{T}; t) \longrightarrow \mathbb{B}(\mathbf{x}^t, \mathbf{x}^t) \tag{4.3}$$

given by $\pi|_{\mathfrak{D}_f}^{-1}(t') = \{t'\} \times \bar{\pi}|_{\mathfrak{D}_f}(t'), t' \in \mathbb{C},$. If we fix $\mathfrak{O}$ a base set of braids we have by composition the braid monodromy

$$\nabla_{t,\mathfrak{O}} : \pi_1(T \setminus \mathcal{T}; t) \xrightarrow{(\bar{\pi}|_{\mathfrak{D}_f})_*} \mathbb{B}(\mathbf{x}^t, \mathbf{x}^t) \xrightarrow{\mathbb{I}_{\mathfrak{O},\mathbf{x}^t,\mathbf{x}^t}} \mathbb{B}_k \tag{4.4}$$

The indices $\mathfrak{O}$ and t will be dropped if they are clear from the context.

4.1. **A model of the regular fiber.** Let us consider $t \in T \setminus \mathcal{T}$ and $(\varphi_1, \ldots, \varphi_k)$ geometric basis of $\pi_1(X \setminus \mathbf{x}^t; *), * \in \partial X$. We lift in $V_t(f)$ (according to (4.1)) the sets

$$\bigcup_{1 \leq i \leq k} \operatorname{Supp}(\varphi_i) \cup D_{\varphi_i} \setminus \{x_{\varphi_i}\} \text{ and } X \setminus \bigcup_{1 \leq i \leq k} (\operatorname{Supp}(\varphi_i) \cup D_{\varphi_i})$$

and we glue them with the lifting of $\varphi_k \cdot \ldots \cdot \varphi_1$. With this we obtain a topological model of $V_t(f) \setminus \pi|_{V_t(f)}^{-1}(\mathbf{x}^t)$ that can be extended to $V_t(f)$ by gluing the lifting of $\mathbf{x}^t$.

Notation 4.2. We denote by $m_t : \pi_1(X \setminus \mathbf{x}^t; *) \to \Sigma_N$ the classical monodromy associated with (4.1) and by $l^{m_t(\alpha)}$ the image of $l \in \{1, \ldots, N\}$ by the permutation $m_t(\alpha), \alpha \in \pi_1(X \setminus \mathbf{x}^t; *)$.

In this subsection we consider the following hypothesis.

Hypothesis 4.3. The permutations $m_t(\varphi_i)$ are transpositions (a_i, b_i) with $a_i \neq b_i$ and $1 \leq a_i, b_i \leq N$.

Notation 4.4. For every $i = 1, \ldots, k$ and $l = 1, \ldots, N$ we denote by:

(1) $(*, y_1), \ldots, (*, y_N)$ the lifting of $* \in \partial X$ in $V_t(f)$.
(2) $(\alpha)_l$ the lifting based at $(*, y_l)$ of the path α with support in $X \setminus \mathbf{x}^t$ and based at $* \in \partial X$.
(3) $(D_i)_l$ the compact component of the lifting of $\operatorname{Supp}(\varphi_i) \cup D_{\varphi_i}$ in $V_t(f)$ which has the point $(*, y_l), l \neq a_i, b_i$, and $(D_i)_{\bar{l}}$ with $\bar{l} := \min\{a_i, b_i\}$ (minimum by convention) which has the points $(*, y_{a_i})$ and $(*, y_{b_i})$.

The topological model of $V_t(f)$ defines a 2-dimensional CW-complex $\mathfrak{K}$ with chain groups

$$C_0(\mathfrak{K}) :=< [1], \ldots, [N] >, C_1(\mathfrak{K}) :=< (\varphi_i)_l \mid i = 1, \ldots, k\,, l = 1, \ldots, N > \text{ and}$$

$$C_2(\mathfrak{K}) :=< (D_i)_l \mid i = 1, \ldots, k, \,, l = 1, \ldots, N, \, l \neq \max\{a_i, b_i\} >$$

and boundary operators ∂_1 and ∂_2 defined by

$$\partial_1((\varphi_i)_l) := [l^{m_t(\varphi_i)}] - [l] = \begin{cases} 0 & \text{if } l \neq a_i, b_i \\ [b_i] - [a_i] & \text{if } l = a_i \\ [a_i] - [b_i] & \text{if } l = b_i \end{cases} \tag{4.5}$$

$$\partial_2(D_{i,l}) := \begin{cases} (\varphi_i)_l & \text{if } l \neq \min\{a_i, b_i\} \\ (\varphi_i)_{a_i} + (\varphi_i)_{b_i} & \text{if } l = \min\{a_i, b_i\} \end{cases} \tag{4.6}$$

We obtain the homology $H_1(V_t(f)) := Z_1(\mathfrak{K})/B_1(\mathfrak{K})$ where $Z_1(\mathfrak{K}) := \operatorname{Ker} \partial_1$ and $B_1(\mathfrak{K}) := \operatorname{Im} \partial_2$. By (4.6) it has the following relations

$$(\varphi_i)_l = 0 \text{ if } l \neq a_i, b_i \text{ and } (\varphi_i)_{a_i} + (\varphi_i)_{b_i} = 0. \tag{4.7}$$

Lemma 4.5. *The path* $(\varphi_i^\epsilon)_l, \epsilon \in \{1, -1\}$, *is such that* $\partial_1((\varphi_i^\epsilon)_l) = [l^{m_t(\varphi_i)}] - [l]$ *and its class in* $C_1(\mathfrak{K})/B_1(\mathfrak{K})$ *is* $(\varphi_i)_l$.

Proof. By uniqueness of lifting

$$(\varphi_i^{-1})_l = \begin{cases} (\varphi_i)_l^{-1} & \text{if } l \neq a_i, b_i \\ (\varphi_i)_{b_i}^{-1} & \text{if } l = a_i \\ (\varphi_i)_{a_i}^{-1} & \text{if } l = b_i \end{cases}$$

Then the path $(\varphi_i^\epsilon)_l$ as element in $C_1(\mathfrak{K})$ is

$$(\varphi_i^\epsilon)_l = \begin{cases} \epsilon \cdot (\varphi_i)_{b_i} & \text{if } \epsilon = -1 \text{ and } l = a_i \\ \epsilon \cdot (\varphi_i)_{a_i} & \text{if } \epsilon = -1 \text{ and } l = b_i \\ \epsilon \cdot (\varphi_i)_l & \text{other cases.} \end{cases}$$

The lemma is deduced by computing ∂_1 (as described in (4.5)), the equality $m_t(\varphi_i^\epsilon) = m_t(\varphi_i)$ and using the relations (4.7). $\square$

Proposition 4.6. *Let* $\alpha = \varphi_{i_1}^{\epsilon_1} \cdot \ldots \cdot \varphi_{i_n}^{\epsilon_n}$, $\epsilon_s \in \{1, -1\}$ *expressed in the geometric basis and* $l \in \{1, \ldots, N\}$. *If we write in a recursive way*

$$l(s+1) := \begin{cases} l & \text{if } s = 0 \\ l(s)^{m_t(\varphi_{i_s}^{\epsilon_s})} = l(s)^{m_t(\varphi_{i_s})} & \text{if } 1 \leq s \leq n \end{cases}$$

then

(a) $(\alpha)_l = (\varphi_{i_1})_{l(1)} + (\varphi_{i_2})_{l(2)} + \cdots + (\varphi_{i_n})_{l(n)}$ *in* $C_1(\mathfrak{K})/B_1(\mathfrak{K})$.
(b) $(\alpha^{-1})_{l^{m_t(\alpha)}} = -(\alpha)_l$ *in* $C_1(\mathfrak{K})/B_1(\mathfrak{K})$.
(c) $(\alpha)_l \in Z_1(\mathfrak{K})$ *if and only if* $l^{m_t(\alpha)} = l$.

Proof. Since $(\alpha)_l = \prod_{s=1}^n (\varphi_{i_s}^{\epsilon_s})_{l(s)}$, then by the second part of Lemma 4.5 we have $(\alpha)_l = \sum_{s=1}^n (\varphi_{i_s})_{l(s)}$ as an element of $C_1(\mathfrak{K})/B_1(\mathfrak{K})$ so we have (a).

To prove (b) we proceed by induction. If $n = 1$ then $\alpha = \varphi_i^\epsilon$. By the second part of Lemma 4.5 and the equality $m_t(\varphi_i^\epsilon) = m_t(\varphi_i) = (a_i, b_i)$, we have in $C_1(\mathfrak{K})/B_1(\mathfrak{K})$

$$(\varphi_i^{-\epsilon})_{l^{m_t(\varphi_i^\epsilon)}} = (\varphi_i)_{l^{m_t(\varphi_i)}} = \begin{cases} 0 = -(\varphi_i)_l, l \neq a_i, b_i \\ (\varphi_i)_{b_i} = -(\varphi_i)_{a_i} = -(\varphi_i^\epsilon)_{a_i}, l = a_i \\ (\varphi_i)_{a_i} = -(\varphi_i)_{b_i} = -(\varphi_i^\epsilon)_{b_i}, l = b_i \end{cases}$$

Then (b) is true for $n = 1$. We suppose (b) is true for $n - 1$ and we denote $\tilde{\alpha} := \varphi_{i_1}^{\epsilon_1} \cdot \ldots \cdot \varphi_{i_{n-1}}^{\epsilon_{n-1}}$. Then

$$(\alpha^{-1})_{l^{m_t(\alpha)}} = (\varphi_{i_n}^{-\epsilon_n})_{l(n)^{m_t(\varphi_{i_n})}} \cdot (\tilde{\alpha}^{-1})_{l^{m_t(\tilde{\alpha})}}$$

and by hypothesis of induction we have in $C_1(\mathfrak{K})/B_1(\mathfrak{K})$

$$(\alpha^{-1})_{l^{m_t(\alpha)}} = (\varphi_{i_n}^{-\epsilon_n})_{l(n)^{m_t(\varphi_{i_n})}} + (\tilde{\alpha}^{-1})_{l^{m_t(\tilde{\alpha})}} = -(\varphi_{i_n}^{\epsilon_n})_{l(n)} - (\tilde{\alpha})_l = -(\alpha)_l.$$

Hence (b) is true.

To prove (c), from the first part of Lemma 4.5, we have

$$\partial_1((\alpha)_l) = \sum_{s=1}^n \partial_1((\varphi_{i_s}^{\epsilon_s})_{l(s)}) = \sum_{s=1}^n ([l(s+1)] - [l(s)]) = [l(n+1)] - [l(1)]$$

then $(\alpha)_l \in Z_1(\mathfrak{K})$ if and only if $l(n+1) = l(1) = l$. Finally since $l(n+1) = l^{m_t(\alpha)}$ we proof (c). $\square$

Notation 4.7. Let $\mathfrak{D}$ a base set of braids. Since $\Psi_{\tau_{\mathbf{x}^t}, \mathfrak{D}}$ is an isomorphism, for $\alpha \in \pi_1(X \setminus \mathbf{x}; *)$ we will denote $(\alpha)_l$ and $m_t(\alpha)$ the lifting $(\alpha^{\tau_{\mathbf{x}^t}, \mathfrak{D}})_l$ and permutation $m_t(\alpha^{\tau_{\mathbf{x}^t}, \mathfrak{D}})$, if no ambiguity seems likely to arise.

4.2. **Discriminant method for a Morse polynomial.** In this section we consider the following hypothesis.

Hypothesis 4.8.

i. f is a Morse function with critical points $P = \{(x_i, y_i)\} \subset \operatorname{Int}(X) \times \operatorname{Int}(Y)$ and $\mu(f)$ critical values $f(P) = \{t_i\} \subset \operatorname{Int}(T)$.
ii. $\mathfrak{D}_f$ is reduced.
iii. If $(t_o, x_o) \in \operatorname{Sing}(\mathfrak{D}_f)$ then $t_o \notin f(P) \cup \partial T$.

By Hypothesis 4.8 we have $\mathcal{T} \cap \partial T = \emptyset$ and the set $\mathcal{T}_{Sing}$ is finite and disjoint with $f(P)$.

Definition 4.9. A list of paths $(\gamma_1, \dots, \gamma_{\mu(f)})$ is said a *distinguished basis of f based at $\star \in \partial T$* if it is a basis of $\pi_1(T \setminus f(P); \star)$ with $\mathrm{Supp}(\gamma_i) \subset \mathrm{Int}(T) \setminus \mathcal{T}$ and there exist homotopy representatives $\tilde{\gamma}_i$ of γ_i such as $(\tilde{\gamma}_1, \dots, \tilde{\gamma}_{\mu(f)})$ is a geometric basis of $\pi_1(T \setminus f(P); \star)$.

Theorem 4.10. *Let $f \in \mathbb{C}[x, y]$ be a monic polynomial of degree N in the variable y which satisfies Hypothesis 4.8 and let $(\gamma_1, \dots, \gamma_{\mu(f)})$ be a distinguished basis of f based at $\star \in \partial T$. Let $\mathfrak{D}$ be a base set of braids and $(\mu_1, \dots, \mu_k)$ as in Example 2.3 with k the degree of $d_f(t, x)$ in the variable x. Then for any $j \in \{1, \dots, k\}$:*

- *(1) There exists a braid $\beta_i \in \mathbb{B}_k$, depending on j, such that $\nabla_{\star,\mathfrak{D}}(\gamma_i) = \beta_i^{-1}\sigma_j\beta_i$.*
- *(2) With Notation 4.7 for the isomorphism $\Psi_{\tau_{\mathbf{x}^\star},\mathfrak{D}}$ we have:*
  - *(a) The permutation $m_\star(\mu_j^{\beta_i})$ is a transposition $(a_i, b_i), 1 \leq a_i < b_i \leq N$.*
  - *(b) If we denote $\delta := \mu_{j+1} \cdot \mu_j \subset X \setminus \mathbf{x}$, then*
    - *(i) $(\Delta_1, \dots, \Delta_{\mu(f)})$ with $\Delta_i := (\delta^{\beta_i})_{a_i}$ defines a distinguished basis of vanishing 1-cycles in $H_1(V_\star(f))$. Also the cycle Δ_i is the first non homologically zero lifting in $((\delta^{\beta_i})_1, \dots, (\delta^{\beta_i})_N)$.*
    - *(ii) If we denote $\beta_{s,i} := \beta_s\nabla_{\star,\mathfrak{D}}(\gamma_i) \in \mathbb{B}_k$, the Picard-Lefschetz operators $(h_{\gamma_i})_*$ satisfy $(h_{\gamma_i})_*(\Delta_s) = (\delta^{\beta_{s,i}})_{a_s}$. Also the cycle $(h_{\gamma_i})_*(\Delta_s)$ is the unique lifting in $((\delta^{\beta_{s,i}})_1, \dots, (\delta^{\beta_{s,i}})_N)$ that can be written in homology as $\Delta_s - n\Delta_i$ for some $n \in \mathbb{Z}$.*

We will prove Theorem 4.10 in Section 6. Note that the paths δ^{β_i} give us the vanishing cycles and $\delta^{\beta_{s,i}} = \Psi_{\nabla_{\star,\mathfrak{D}}(\gamma_i)}(\delta^{\beta_s})$ describes the Picard-Lefschetz operators. Hence we define:

Definition 4.11. For $i = 1, \dots, \mu(f)$ paths δ^{β_i} are said *vanishing paths* and isomorphisms $\Psi_{\nabla_{\star,\mathfrak{D}}(\gamma_i)}$ *Picard-Lefschetz transformations.*

Theorem 4.10 shows us how to compute, in an algebraic way, the elements Δ_i and $(h_{\gamma_s})_*(\Delta_i)$. To do this we need some extra data. To simplify notation we denote by γ_0 the identity path onto $\star$ and so we can extend the definition of the $\beta_{s,i}$ to $\beta_{s,0} := \beta_s\nabla_{\star,\mathfrak{D}}(\gamma_0)$. The extra data are:

- (a) The list of permutations $(m_\star(\mu_1^{\tau_{\mathbf{x}^\star},\mathfrak{D}}), \dots, m_\star(\mu_k^{\tau_{\mathbf{x}^\star},\mathfrak{D}}))$ as elements of the permutation group Σ_N.
- (b) If we fix, for example, $j = 1$, a representative of $\nabla_{\star,\mathfrak{D}}(\gamma_i), i = 1, \dots, \mu(f)$, in the braid group $\mathbb{B}_k$ which is written as $\beta_i^{-1}\sigma_1\beta_i$.

With these data we compute Δ_i and $(h_{\gamma_i})_*(\Delta_s)$ algebraically as follows:

1) By (2.2) we compute the paths $\mu_1^{\beta_{s,i}}$ and $\mu_2^{\beta_{s,i}}$ expressed in the geometric basis $(\mu_1, \dots, \mu_k)$.
2) We compute the transposition $(a_s, b_s) = m_\star(\mu_1^{\beta_{s,0}\tau_{\mathbf{x}^\star},\mathfrak{D}})$ using (a).
3) We lift $\delta^{\beta_{s,i}} = \mu_2^{\beta_{s,i}} \cdot \mu_1^{\beta_{s,i}}$ at the point a_s as it is showed by Proposition 4.6(a) (using the geometric basis $(\mu_1^{\tau_{\mathbf{x}^\star},\mathfrak{D}}, \dots, \mu_k^{\tau_{\mathbf{x}^\star},\mathfrak{D}})$) to obtain Δ_i and $(h_{\gamma_s})_*(\Delta_i)$.

Items (2) and (3) above can be merged into an unique point:

- (2') For $l = 1, \dots, N$, with Proposition 4.6(a) we lift $(\delta^{\beta_{s,0}})_l$ until we obtain a non-zero element in homology and we lift $(\delta^{\beta_{s,i}})_l$ until it can be written in homology as $\Delta_s - n\Delta_i$ for some $n \in \mathbb{Z}$.

Remark 4.12. To use Theorem 4.10 in an effective way we can observe that:

1) If f verifies (i) and (ii) in Hypothesis 4.8 then one can check the condition $(t_o, x_o) \in \mathrm{Sing}(\mathfrak{D}_f) \Rightarrow t_o \notin f(P)$, as in (iii), if either every t_i is a simple root of the polynomial $\mathrm{discrim}_x(d_f(t, x)) \in \mathbb{C}[t]$ or if every $\nabla_{\star,\mathfrak{D}}(\gamma_i)$ is a conjugated of $\sigma_1 \in \mathbb{B}_k$. Finally, condition $(t_o, x_o) \in \mathrm{Sing}(\mathfrak{D}_f) \Rightarrow t_o \notin \partial T$, is true with only a small perturbation of T.

2) It is not necessary to find X in Hypothesis 4.8 explicitly. Let $\tilde{X} \subset \mathbb{C}$ be a disk with $\mathbf{x}^\star \subset \operatorname{Int}(\tilde{X})$ and $\tilde{*} \in \partial\tilde{X}$. Let $(\tilde{\mu}_1, \ldots, \tilde{\mu}_k)$ be a geometric basis of $\pi_1(\tilde{X} \setminus \mathbf{x}^\star; \tilde{*})$ such that there exists a path r that begins at $*$ and ends at $\tilde{*} \in \mathbb{C}$ so that
$$\mu_j^{\tau_{\mathbf{x}^\star,\mathfrak{D}}} = r \cdot \tilde{\mu}_j \cdot r^{-1}$$
in the group $\pi_1(\mathbb{C} \setminus \mathbf{x}^\star; *)$. Hence $m_\star(\tilde{\mu}_j)$ and $m_\star(\mu_j^{\tau_{\mathbf{x}^\star,\mathfrak{D}}})$ are conjugated by a permutation and if we define the braid $\tilde{\beta}_{s,i} := \tau_{\mathbf{x}^\star,\mathfrak{D}}^{-1}\beta_{s,i}\tau_{\mathbf{x}^\star,\mathfrak{D}}$ and we write $\mu_j^{\beta_{s,i}} = \mu_{j_1}^{\epsilon_1} \cdot \ \ldots \cdot \ \mu_{j_m}^{\epsilon_m}$, $\epsilon_n \in \{-1, 1\}$, then one has
$$\begin{aligned} \mu_j^{\beta_{s,i}\tau_{\mathbf{x}^\star,\mathfrak{D}}} &= \Psi_{\tau_{\mathbf{x}^\star,\mathfrak{D}}}(\mu_j^{\beta_i}) = \Psi_{\tau_{\mathbf{x}^\star,\mathfrak{D}}}(\mu_{j_1}^{\epsilon_1} \cdot \ldots \cdot \mu_{j_m}^{\epsilon_m}) \\ &= r \cdot \tilde{\mu}_{j_1}^{\epsilon_1} \cdot \ldots \cdot \tilde{\mu}_{j_m}^{\epsilon_m} \cdot r^{-1} = r \cdot \tilde{\mu}_j^{\tilde{\beta}_{s,i}} \cdot r^{-1}. \end{aligned} \tag{4.8}$$

   It is easy to prove that permutation $m_\star(\tilde{\mu}_j^{\tilde{\beta}_{i,0}})$ is a transposition, say $(\tilde{a}_i, \tilde{b}_i)$, $1 \leq \tilde{a}_i < \tilde{b}_i \leq N$, and if we define $\tilde{\delta} := \tilde{\mu}_{j+1} \cdot \tilde{\mu}_j$, the elements $(\tilde{\delta}^{\tilde{\beta}_{s,i}})_{\tilde{a}_i}$, are, up to sign, $(h_{\gamma_i})_*(\Delta_s)$. Furthermore, by (4.8), computing $(\tilde{\delta}^{\tilde{\beta}_{s,i}})_{\tilde{a}_i}$ only requires computing $\delta^{\beta_{s,i}}$ using (2.2), changing every $\mu_{j_n}^{\epsilon_n}$ by $\tilde{\mu}_{j_n}^{\epsilon_n}$ and, with the list of permutations $(m_\star(\tilde{\mu}_1), \ldots, m_\star(\tilde{\mu}_k)) \subset \Sigma_N^k$, computing the lifting at the point $\tilde{a}_i$ as it is showed by Proposition 4.6(a). In other words, up to sign, $(h_{\gamma_i})_*(\Delta_s), i = 0, 1, \ldots, \mu(f)$, only needs $\beta_{s,i}$ and $(m_\star(\tilde{\mu}_1), \ldots, m_\star(\tilde{\mu}_k))$.

3) If we decompose $\nabla_{\star,\mathfrak{D}}(\gamma_i) = \beta_i^{-1}\sigma_{j(i)}\beta_i$ for some $j(i), 1 \leq j(i) \leq k$, depending on i, by Lemma 2.12 we obtain $\nabla_{\star,\mathfrak{D}}(\gamma_i) = (\beta_i\alpha_{j(i)})^{-1}\sigma_1\alpha_{j(i)}\beta_i$ and the equality $\mu_1^{\alpha_{j(i)}\beta_i} = \mu_{j(i)}^{\beta_i}$. Then $(a_i, b_i) = m_\star(\mu_{j(i)}^{\beta_i})$ and, if we define $\delta_i := \mu_{j(i)+1} \cdot \mu_{j(i)}$, $\delta^{\alpha_{j(i)}} = \delta_i$. So $(\delta_i^{\beta_i})_{a_i}$ and $(\delta_s^{\beta_s\nabla(\gamma_i)})_{a_s}$ are Δ_i and $(h_{\gamma_i})_*(\Delta_s)$, again.

Finally note that, by Picard-Lefschetz Theorem, the element n defined in Theorem 4.10(2.b.ii) is the intersection number between the vanishing cycles Δ_s and Δ_i, i.e., $n = (\Delta_s, \Delta_i)$. As a corollary we have:

Corollary 4.13. *Let $E(\sigma_j)$ be the stabilizer of σ_j by the action $\Phi_{\mathbf{x},\mathbf{x}}$ given in* (2.2). *If $\delta^{\beta_s\beta_i^{-1}} \in E(\sigma_j)$ then $(\Delta_s, \Delta_i) = 0$.*

Proof. In homotopy we have $\delta^{\beta_{s,i}} = \delta^{\beta_s\beta_i^{-1}\sigma_j\beta_i} = \delta^{\beta_s}$, then by Theorem 4.10 we have $(h_{\gamma_i})_*(\Delta_s) = \Delta_s$. ☐

Remark 4.14. Since $\delta^{\beta_i\beta_i^{-1}} = \delta \in E(\sigma_j)$ by Corollary 4.13 we have $(\Delta_i, \Delta_i) = 0$ which is already known in the case of two variables (see for example [3, Lemma 1.4]).

4.3. **Discriminant method for tame polynomials.** In this section we consider the following hypothesis.

Hypothesis 4.15. The polynomial application f is tame.

Definition 4.16. We will call a morsification of f which satisfies Hypothesis 4.8 a *good morsification.*

Proposition 4.17. *Almost every perturbation $f_{\lambda,a}(x, y) := f(x + \lambda y, y) + ax$ of f, $\lambda, a \ \in \mathbb{C}, |\lambda|, |a|$ sufficiently small, is a good morsification of f.*

Proof. Since f has isolated singularities, by Lemma 3.6 the discriminant $\mathfrak{D}_{f_{\lambda,0}}$ is reduced in $T \times \mathbb{C}$ for almost every $\lambda \in \mathbb{C}$. Let $\lambda \in \mathbb{C}$ be so that $\mathfrak{D}_{f_{\lambda,0}}$ is reduced in $T \times \mathbb{C}$. The polynomial $f_{\lambda,0}$ is tame because f is. Then $f_{\lambda,0}$ is regular at infinity and hence the leader coefficient of $d_{f_{\lambda,0}}(t, x)$, as polynomial in the variable x, is a non-zero constant and therefore $\mathfrak{D}_{f_{\lambda,0}}$ has no vertical asymptotes.

Let $|\lambda|$ be small enough such that the critical points of $f_{\lambda,0}$ are inside M. Since the discriminant curve $\mathfrak{D}_{f_{\lambda,0}}$ has a finite number of singularities and inflection points in $T \times X$, a generic linear transformation

$$\{(t,x) \in T \times \mathbb{C} \mid d_{f_{\lambda,0}}(t - ax, t) = 0\}, a \in \mathbb{C},$$

with $|a|$ sufficiently small, is again reduced and has no vertical asymptotes and also vertical lines $\{t = t_o\}, t_o \in \mathbb{C}$, are not tangent to singular points or inflection points. This curve is the discriminant $\mathfrak{D}_{f_{\lambda,a}}$.

Discriminant $\mathfrak{D}_{f_{\lambda,a+\tilde{a}}}$, with $|\tilde{a}|$ sufficiently small, has the same properties in $T \times \mathbb{C}$ that $\mathfrak{D}_{f_{\lambda,a}}$ and also every vertical line $\{t = t_o\}$ is at most tangent at a smooth (non-inflexion) point and if it is tangent then there is no critical point on it.

From the properties of $\mathfrak{D}_{f_{\lambda,a+\tilde{a}}}$, Corollary 3.4 and Lemma 3.5 one obtains that the polynomial $f_{\lambda,a+\tilde{a}}$ has no degenerated singularities in $f^{-1}_{\lambda,a+\tilde{a}}(T)$. Also, if $|a+\tilde{a}|$ is sufficiently small, $f_{\lambda,a+\tilde{a}}$ has no other singularities, because f_λ is tame, and they are in $\mathrm{Int}(X) \times \mathrm{Int}(Y)$. □

By Proposition 4.17 we deduce the existence of good morsifications of f and thus we have the following theorem.

Theorem 4.18. *Local monodromies of a tame polynomial $f(x,y)$ which is monic in the variable y can be computed in an algebraic effective way using a good morsification $\tilde{f}$ of f and Theorem 4.10 for $\tilde{f}$.*

Remark 4.19. If f is good at infinity but not tame we can use Theorem 4.18 with a good morsification $\tilde{f}$ but we must distinguish between the critical values of $\tilde{f}$ that come from the morsification of affine critical points of f and the ones that come from critical points at infinity of f.

5. TOPOLOGY OF CONJUGATED POLYNOMIALS

At the present section we show two polynomial applications f^+ and f^-, conjugated in a number field that are not topologically equivalent.

5.1. A uniparametric family of polynomials.

We consider the family of polynomials $f^s(x,y) := c(x,y)r^s(x,y), s \in \mathbb{C}$, given by the product of a cubic curve $c(x,y) := y^2x - (y+1)^3$ and a line $r^s(x,y) := s^2(2s-3)y + x - 3s^2$.

The polynomial $f^s(x,y)$, with s generic, is such that:

1. The zero fiber is singular with singularities $\mathbb{A}_1$ and $\mathbb{A}_3$.
2. There are critical values $t_1^s, t_2^s \neq 0$ with only one singularity $\mathbb{A}_1$ over their fibers.
3. The other fibers are smooth.
4. It is tame.

Then if $s_1, s_2 \in \mathbb{C}$ are generic, the polynomial applications $f^{s_i} : \mathbb{C}^2 \to \mathbb{C}, i = 1,2$, are topologically equivalent because they are in a uniparametric equisingular family and they have the same link at infinity.

We write the homogeneous polynomial $F^s(x,y,z)$ associated with $f^s(x,y)$. If we compute a Gröbner basis (with respect to the lexicographic order given by (x,y,t)) of the ideal $\langle F^s_x(x,y,1), F^s_y(x,y,1), F^s(x,y,1) - t\rangle$, the polynomial

$$(256s^2 + 256s + 64)t^2 + (-1647s^4 - 1836s^3 + 2430s^2 + 2916s + 729)t + 2916s^6$$

belongs to this ideal. Its discriminant with respect to the variable t is

$$-2187(s-1)^2(s-3-2\sqrt{3})^2(s-3+2\sqrt{3})^2(5s+3)^2.$$

Then the critical values t_1^s and t_2^s are equal if $s = 3 \pm 2\sqrt{3}$. We write $f^+ := f^{3+2\sqrt{3}}$ and $f^- := f^{3-2\sqrt{3}}$. These polynomials satisfy again the properties (1), (3) and (4) and they have only one non-zero critical value ($t^+ := t^{3+2\sqrt{3}}$ and $t^- := t^{3-2\sqrt{3}}$ respectively), with two singularities $\mathbb{A}_1$ in the singular fiber $V_{t^\pm}(f^\pm)$.

Since the polynomials f^+ and f^- are conjugated in the number field $\mathbb{Q}(\sqrt{3})$, they have the same algebraic properties. The reason is the existence of the Galois isomorphism between the two of them. Also the pairs of quartics $V_0(f^\pm)$, $V_{t^\pm}(f^\pm)$, and $V_t(f^\pm), t \neq 0, t^\pm$, are diffeomorphic because they have the same combinatorial properties (see, for example, classification in [22, Section 2.2], [11]). In what follows we will prove that, the polynomial applications f^+ and f^-, are not topologically equivalent.

If f^+ and f^- were topologically equivalent then there would exist Θ and θ homeomorphisms such that the diagram

$$\begin{tikzcd}
\mathbb{C}^2 \arrow[r, "\Theta"] \arrow[d, "f^+"'] \arrow[dr, phantom, "\circlearrowleft"] & \mathbb{C}^2 \arrow[d, "f^-"] \\
\mathbb{C} \arrow[r, "\theta"] & \mathbb{C}
\end{tikzcd} \tag{5.1}$$

is commutative. Then Θ sends singular fibers to singular fibers and θ critical values to critical values. Since both singular fibers are not homeomorphic, θ must send 0 to 0 and t^+ to t^- respectively. Finally note that, using the complex conjugation $\bar{\ }: z \mapsto \bar{z}$ if necessary (changing Θ by $\bar{\Theta}$, and θ by $\bar{\theta}$), we can assume that θ preserves the orientation.

Let T be a geometric disk containing 0 and $t^\pm$, also let $\star^\pm \in \partial T$ be regular values of $f^\pm$ and $r : [0,1] \to \mathbb{C}$ a path with support in $T \setminus \{0, t^-\}$ such that $r(0) = \theta(\star^+)$ and $r(1) = \star^-$. The pair of homeomorphism θ and path r induces the group isomorphism

$$\begin{array}{cccc}
\theta_* : & \pi_1(T \setminus \{0, t^+\}; \star^+) & \longrightarrow & \pi_1(T \setminus \{0, t^-\}; \star^-) \\
& \gamma & \mapsto & r^{-1} \cdot \theta(\gamma) \cdot r.
\end{array}$$

Let h_r be a diffeomorphism given by lifting the path r. The pair of homeomorphism Θ and diffeomorphism h_r induces the isomorphism

$$\begin{array}{cccc}
\Theta_* : & H_1(V_{\star^+}(f^+)) & \longrightarrow & H_1(V_{\star^-}(f^-)) \\
& \Delta & \mapsto & (h_r)_*(\Theta(\Delta))
\end{array}$$

of free Abelian groups of rank $\mu(f^\pm) = \mu(\mathbb{A}_1) + \mu(\mathbb{A}_3) + \mu(\mathbb{A}_1) + \mu(\mathbb{A}_1) = 6$.

Let $\mathcal{B}^\pm$ be a basis in $H_1(V_{\star^\pm}(f^\pm))$, then Θ_* is given by an invertible matrix $P_\Theta \in \mathrm{GL}(6, \mathbb{Z})$ which induce the group isomorphism

$$\begin{array}{ccccccc}
\mathrm{Aut} H_1(V_{\star^+}(f^+)) & \overset{\mathcal{B}^+}{\cong} & \mathrm{GL}(6,\mathbb{Z}) & \xrightarrow{\Theta^*} & \mathrm{GL}(6,\mathbb{Z}) & \overset{\mathcal{B}^-}{\cong} & \mathrm{Aut} H_1(V_{\star^-}(f^-)) \\
& & P & \mapsto & P_\Theta^{-1} P P_\Theta & &
\end{array}$$

The commutativity of the diagram (5.1) and the isomorphisms of groups θ_* and Θ^* induce the commutative diagram given by the homologic monodromies of $f^\pm$, $\rho_*^\pm : \gamma \to (h_\gamma)_*$:

$$\begin{tikzcd}
\pi_1(T \setminus \{0, t^+\}; \star^+) \arrow[r, "\rho_*^+"] \arrow[d, "\theta_*"'] \arrow[dr, phantom, "\circlearrowleft"] & \mathrm{Aut} H_1(V_{\star^+}(f^+)) \overset{\mathcal{B}^+}{\cong} \mathrm{GL}(6,\mathbb{Z}) \arrow[d, "\Theta^*"] \\
\pi_1(\mathbb{C} \setminus \{0, t^-\}; \star^-) \arrow[r, "\rho_*^-"] & \mathrm{Aut} H_1(V_{\star^-}(f^-)) \overset{\mathcal{B}^-}{\cong} \mathrm{GL}(6,\mathbb{Z})
\end{tikzcd} \tag{5.2}$$

Let $(\gamma_1^\pm, \gamma_0^\pm)$ be geometric bases of $\pi_1(T \setminus \{0, t^\pm\}; \star^\pm)$ where $\gamma_0^\pm$ are meridians of 0 and $\gamma_1^\pm$ are meridians of $t^\pm$. Since $\theta(0) = 0$ and $\theta(t^+) = t^-$, $\theta_*(\gamma_0^+)$ is conjugated to γ_0^-, $\theta_*(\gamma_1^+)$ is conjugated to γ_1^-, and $\theta_*(\gamma_0^+ \cdot \gamma_1^+)$ is conjugated to $\gamma_0^- \cdot \gamma_1^-$. Therefore there exists $\gamma \in \pi_1(T \setminus \{0, t^+\}; \star)$ such that

$$\theta_*(\gamma) \cdot \theta_*(\gamma_0^+) \cdot \theta_*(\gamma_1^+) \cdot \theta_*^{-1}(\gamma) = \gamma_0^- \cdot \gamma_1^-.$$

Thus if we consider

$$\tilde{\gamma}_i^+ := \gamma \cdot \gamma_i^+ \cdot \gamma^{-1}, \tag{5.3}$$

the new basis $(\tilde{\gamma}_1^+, \tilde{\gamma}_0^+)$ is such that $\theta_*(\tilde{\gamma}_0^+)$ is conjugated to γ_0^-, $\theta_*(\tilde{\gamma}_1^+)$ is conjugated to γ_1^-, and $\theta_*(\tilde{\gamma}_0^+ \cdot \tilde{\gamma}_1^+) = \gamma_0^- \cdot \gamma_1^-$. Therefore $(\theta_*(\tilde{\gamma}_1^+), \theta_*(\tilde{\gamma}_0^+))$ is a geometric basis of the group $\pi_1(T \setminus \{0, t^-\}; \star^-)$.

By Artin Theorem, there exists a Hurwitz move that sends the geometric basis $(\theta_*(\tilde{\gamma}_1^+), \theta_*(\tilde{\gamma}_0^+))$ to the geometric basis (γ_1^-, γ_0^-). This move must have $\sigma_1^{2n} \in \mathbb{B}_2$, $n \in \mathbb{Z}$, as its associated braid since $\theta_*(\tilde{\gamma}_i^+)$ and γ_i^- are conjugated, that is, since fiber order must be respected. Hence

$$\Psi_{\sigma_1^{2n}}(\theta_*(\tilde{\gamma}_i^+)) = \gamma_i^-, \tag{5.4}$$

where $\Psi_{\sigma_1^{2n}}$ is the Hurwitz move associated with σ_1^{2n}.

Remark 5.1. The fact that $f^\pm$ has only two singular non-diffeomorphic fibers makes the study of the commutative diagram (5.1) easier. For example, it was key in order to deduce that the Hurwitz move had to be of type σ_1^{2n}.

Notation 5.2. We denote by $H_0^\pm$ and $H_1^\pm$ the monodromy matrices associated with the operators $(h_{\gamma_0^\pm})_*$ and $(h_{\gamma_1^\pm})_*$ in the bases $\mathcal{B}^\pm$, respectively.

By (5.3) we have $(h_{\tilde{\gamma}_i^+})_* = (h_\gamma)_*^{-1} \circ (h_{\gamma_i^+})_* \circ (h_\gamma)_*$. Thus, if $P_\gamma \in \mathrm{GL}(6, \mathbb{Z})$ is the matrix of $(h_\gamma)_*$ in the basis $\mathcal{B}^+$, then the matrices $P_\gamma^{-1} H_0^+ P_\gamma$ and $P_\gamma^{-1} H_1^+ P_\gamma$ define the monodromy operators $(h_{\tilde{\gamma}_0^+})_*$ and $(h_{\tilde{\gamma}_1^+})_*$ in the basis $\mathcal{B}^+$. Then, using the commutative diagram (5.2), the matrices $P_\Theta^{-1} P_\gamma^{-1} H_0^+ P_\gamma P_\Theta$ and $P_\Theta^{-1} P_\gamma^{-1} H_1^+ P_\gamma P_\Theta$ define the monodromy operators $(h_{\theta_*(\tilde{\gamma}_0^+)})_*$ and $(h_{\theta_*(\tilde{\gamma}_1^+)})_*$ in the basis $\mathcal{B}^-$.

We define

$$\alpha_1 := \gamma_0^- \cdot \gamma_1^-, \alpha_n := \alpha_{n-1}^{\sigma_1^2} \cdot \alpha_1 \text{ if } n > 1.$$

The isomorphism $\Psi_{\sigma_1^{2n}}$ of $\pi_1(T \setminus \{0, t^-\}; \star^-)$ is such that

$$\Psi_{\sigma_1^{2n}}(\varrho) = \begin{cases} \alpha_1 \cdot \varrho \cdot \alpha_1^{-1} & \text{if } n = 1 \\ \alpha_n \cdot \varrho \cdot \alpha_n^{-1} & \text{if } n > 1. \end{cases}$$

Therefore it is an inner automorphism of $\pi_1(T \setminus \{0, t^-\}; \star^-)$. By (5.4), $\gamma_i^-, i = 0, 1$, are conjugated to $\theta_*(\tilde{\gamma}_i^+), i = 0, 1$, by the same element $\alpha_n \in \pi_1(T \setminus \{0, t^-\}; \star^-)$. If we denote by $P_{\alpha_n} \in GL(6, \mathbb{Z})$ the associated matrix to $(h_{\alpha_n})_*$ in the basis $\mathcal{B}^-$ and define $P := P_\gamma P_\Theta P_{\alpha_n}$, then the matrices $P^{-1} H_0^+ P$ and $P^{-1} H_1^+ P$ must define the monodromy operators $(h_{\gamma_0^-})_*$ and $(h_{\gamma_1^-})_*$ in the basis $\mathcal{B}^-$.

By Notation 5.2, if f^+ and f^- were topologically equivalent, then they should satisfy $H_0^- = P^{-1} H_0^+ P$ and $H_1^- = P^{-1} H_1^+ P$ where $P \in GL(6, \mathbb{Z})$, or analogously

$$P\, H_0^- = H_0^+\, P,\ P\, H_1^- = H_1^+\, P \text{ and } \det(P) \neq 0. \tag{5.5}$$

5.2. **Calculus of the homological monodromy.** The polynomials $f^\pm$ are monic, of degree 4 in the variable y, and tame. In order to compute their homological monodromy we can use Theorem 4.18.

Since $d_{f^\pm}(t, x)$ is reduced (since $\mathrm{discrim}_x(d_{f^\pm}(t, x)) \neq 0$) it is enough to consider $f_{0,a}^\pm(x, y) := f^\pm(x, y) + ax, a \in \mathbb{C}$, a morsification of $f^\pm$ verifying Hypothesis 4.8 for appropriate disks T, X and Y. We denote such morsifications by $f_a^\pm$.

Remark 5.3. From now on we will use in this section the lexicographic order $<^{\pi/2}$ (see Notation 2.7), but for the sake of simplicity we will omit any reference to it in the text. Also as coefficients are in $\mathbb{Q}(\sqrt{3})$, we will use a computer program based on a method showed by J. Carmona [10] in order to compute both the braid monodromy associated with the discriminant of $f_a^{\pm}$ and the classical monodromy $m_{\star^{\pm}}$ of $\pi|_{V_{\star^{\pm}}(f_a^{\pm})}$.

The discriminant method for $f^{\pm}$. Let $a := 10^{-1}$ be a sufficiently small constant. For this value $f_a^{\pm}$ is a Morse function with a reduced discriminant and without any vertical asymptotes (since $f_a^{\pm}$ is also tame). The critical values of $f^{\pm}$ and $f_a^{\pm}$ are shown in Figure 6 (note that the critical values associated with the morsification of the singularities $\mathbb{A}_3^0$ and $\mathbb{A}_1^0$ over the zero fiber and the singularities $\mathbb{A}_1^{\pm}$ over the $t^{\pm}$ fiber are enclosed each in a rectangle).

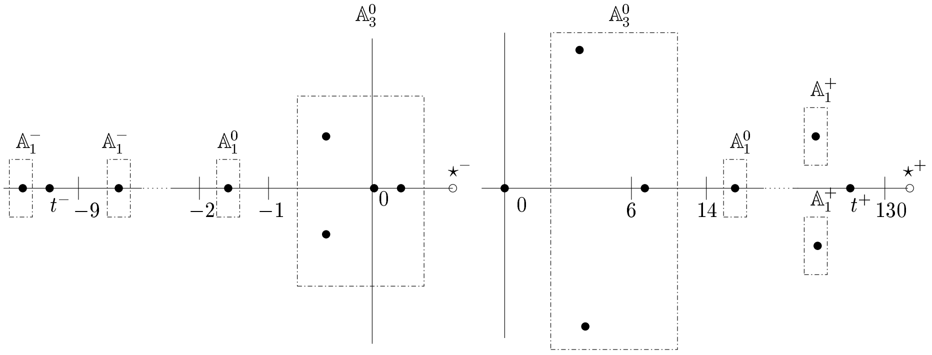

FIGURE 6. Critical values of $f^{\pm}$ and $f_a^{\pm}$.

The points $\star^+ := 132$ and $\star^- := 2$ are regular values of $f^{\pm}$ and $f_a^{\pm}$. We consider the paths given in Figures 7 and 8.

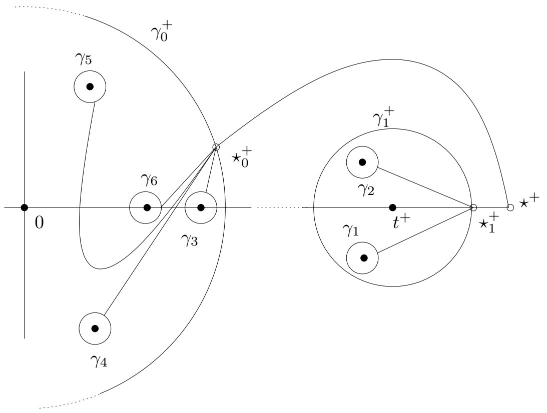

FIGURE 7. Distinguished basis for f_a^+ with $a = 10^{-1}$ and $\star^+ = 132$.

The list $(\gamma_1, \ldots, \gamma_6)$, in each figure, is a distinguished basis of $f_a^{\pm}$ based at $\star^{\pm}$ whereas the list $(\gamma_1^{\pm}, \gamma_0^{\pm})$, is a geometric basis of $\pi_1(T \setminus \{0, t^{\pm}\}; \star^{\pm})$ as considered in Section 5.1.

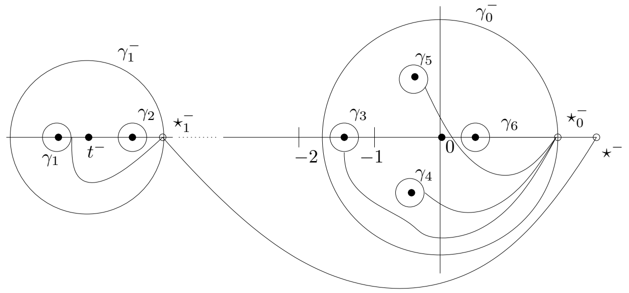

FIGURE 8. Distinguished basis for f_a^- with $a = 10^{-1}$ and $\star^- = 2$.

We denote $b * a := a^{-1}ba$ in $\mathbb{B}_9$. The braid monodromy for $\mathfrak{D}_{f_a^+}$ is:

$$\begin{aligned}
\nabla_{\star^+}(\gamma_1) = &\quad \sigma_2 * \sigma_1^{-1}, \\
\nabla_{\star^+}(\gamma_2) = &\quad \sigma_2 * \sigma_3^{-1}, \\
\nabla_{\star^+}(\gamma_3) = &\quad \sigma_8 * \sigma_7\sigma_6^{-1}\sigma_5^{-1}\sigma_4^{-1}\sigma_3^{-1}\sigma_2^{-1}\sigma_3^{-1}\sigma_7^{-1}, \\
\nabla_{\star^+}(\gamma_4) = &\quad \sigma_5 * \sigma_6\sigma_4^{-1}\sigma_3^{-1}\sigma_4\sigma_7\sigma_6^{-1}\sigma_2^{-1}\sigma_3\sigma_1^{-1}\sigma_2\sigma_5^{-1}\sigma_4^{-1}\sigma_3^{-1}\sigma_2^{-1}\sigma_3^{-1}\sigma_7^{-1}, \\
\nabla_{\star^+}(\gamma_5) = &\quad \sigma_5 * \sigma_6\sigma_4\sigma_7\sigma_6^{-1}\sigma_3\sigma_2\sigma_5^{-1}\sigma_4^{-1}\sigma_3^{-1}\sigma_2^{-1}\sigma_3^{-1}\sigma_7^{-1} \text{ and} \\
\nabla_{\star^+}(\gamma_6) = &\quad \sigma_6 * \sigma_7\sigma_6^{-1}\sigma_5^{-1}\sigma_4^{-1}\sigma_3^{-1}\sigma_2^{-1}\sigma_3^{-1}\sigma_7^{-1}.
\end{aligned} \tag{5.6}$$

The braid monodromy for $\mathfrak{D}_{f_a^-}$ is:

$$\begin{aligned}
\nabla_{\star^-}(\gamma_1) = &\quad \sigma_2 * \sigma_3\sigma_5\sigma_4\sigma_6\sigma_3, \\
\nabla_{\star^-}(\gamma_2) = &\quad \sigma_8 * \sigma_7^{-1}\sigma_8\sigma_7\sigma_6\sigma_7^{-1}\sigma_5\sigma_4\sigma_5\sigma_6\sigma_3, \\
\nabla_{\star^-}(\gamma_3) = &\quad \sigma_1, \\
\nabla_{\star^-}(\gamma_4) = &\quad \sigma_4 * \sigma_5\sigma_6\sigma_3, \\
\nabla_{\star^-}(\gamma_5) = &\quad \sigma_4 * \sigma_5^{-1}\sigma_6^{-1}\sigma_5^{-1}\sigma_3^2 \text{ and} \\
\nabla_{\star^+}(\gamma_6) = &\quad \sigma_7.
\end{aligned} \tag{5.7}$$

Then we obtain the elements $\beta_i, \sigma_{j(i)} \in \mathbb{B}_9$ of Remark 4.12(3) and we deduce, by Remark 4.12(1), that $f_a^{\pm}$ is a good morsification for X and Y geometric disks sufficiently big.

The ordered set of roots of $d_{f_a^{\pm}}(\star^{\pm}, x) = 0$ is the list $\mathbf{x}^{\star^{\pm}} = (x_1^{\pm}, \ldots, x_9^{\pm})$ with

- $x_9^+ > 0$ and $|x_9^+| > |x_i^+|, i = 1, \ldots, 8$.
- $x_1^- < 0$ and $|x_1^-| > |x_i^-|, i = 2, \ldots, 9$.

We want to use Remark 4.12(2). Let us consider two points $\tilde{*}^+ := x_9 + 1$ and $\tilde{*}^- := -x_1 + 1$ and two geometric disks $\tilde{X}^{\pm}$ with center $0 \in \mathbb{C}$ and radius $\tilde{*}^{\pm}$. Let us consider Example 2.3 with X the big disk fixed above and $r^{\pm} := [*, \tilde{*}^{\pm}]$. By Remark 4.12(2) it is enough to know the classical monodromy $m_{\star^{\pm}}$ of the geometric basis $(\tilde{\mu}_1^{\pm}, \ldots, \tilde{\mu}_9^{\pm})$ of the group $\pi_1(\tilde{X} \setminus \mathbf{x}^{\star^{\pm}}; \tilde{*}^{\pm})$ where $\tilde{\mu}_j^{\pm} = (r^{\pm})^{-1} \cdot \mu_j^{\tau_{\mathbf{x}^\star}} \cdot r^{\pm}$.

The classical monodromy $m_{\star^+}$ of the geometric basis $(\tilde{\mu}_1^+, \ldots, \tilde{\mu}_9^+)$ is the list

$$((1,3),(2,3),(1,3),(1,2),(1,4),(1,4),(1,3),(2,3),(1,2)), \tag{5.8}$$

and the classical monodromy $m_{\star^-}$ of the geometric basis $(\tilde{\mu}_1^-, \ldots, \tilde{\mu}_9^-)$ is the list

$$((3,4),(3,4),(1,2),(2,4),(3,4),(2,4),(1,4),(1,4),(2,3)). \tag{5.9}$$

Combining the data (5.6), (5.8) and (5.7), (5.9) we can compute the invariants associated with the homological monodromy of $f^{\pm}$. In particular, let $\mathcal{B}^{\pm}$ the distinguished basis of vanishing cycles obtained by lifting the distinguished bases $(\gamma_1, \ldots, \gamma_6)$ in Figures 7 and 8, then the intersection matrix $\mathbb{I}_{f^{\pm}}$ with respect to $\mathcal{B}^{\pm}$ is:

$$\mathbb{I}_{f^+} = \left[\begin{array}{cc|cccc} 0 & 0 & -1 & 1 & 1 & 1 \\ 0 & 0 & -1 & 0 & 0 & 1 \\ \hline 1 & 1 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 1 & 1 \\ -1 & 0 & 0 & -1 & 0 & 1 \\ -1 & -1 & 0 & -1 & -1 & 0 \end{array}\right] \quad \text{and} \quad \mathbb{I}_{f^-} = \left[\begin{array}{cc|cccc} 0 & 0 & -1 & 1 & 0 & 0 \\ 0 & 0 & 0 & -1 & -2 & -1 \\ \hline 1 & 0 & 0 & 0 & 0 & 0 \\ -1 & 1 & 0 & 0 & 1 & 1 \\ 0 & 2 & 0 & -1 & 0 & 1 \\ 0 & 1 & 0 & -1 & -1 & 0 \end{array}\right], \tag{5.10}$$

where number on the i-th column and the j-th arrow is (Δ_i, Δ_j).

Example 5.4. We will show in detail how to obtain $(\Delta_1, \Delta_3) = 1$ from matrix $\mathbb{I}_{f^+}$. The rest of intersection numbers follow the same pattern.

By Remark 4.12(3) we compute $\mu_2^{\beta_1} = \mu_1$ and $\mu_8^{\beta_3} = \mu_7 \cdot \mu_2 \cdot \mu_7^{-1}$. Transpositions $(\tilde{a}_1, \tilde{b}_1)$ and $(\tilde{a}_3, \tilde{b}_3)$, which are defined in Remark 4.12(2), are

$$m_{\star^+}(\tilde{\mu}_1) = (1,3) \text{ and } m_{\star^+}(\tilde{\mu}_7 \cdot \tilde{\mu}_2 \cdot \tilde{\mu}_7^{-1}) = (1,2).$$

We define $\tilde{a}_i$ to be the lowest in $\{\tilde{a}_i, \tilde{b}_i\}, i = 1,3$. This choice only produces a change of orientation in the vanishing cycles. Thus we have $\tilde{a}_1 = \tilde{a}_3 = 1$.

By Remark 4.12(3) again, vanishing paths are

$$\begin{array}{rcccl} \delta_1^{\beta_1} & = & \mu_2^{\beta_1} \cdot \mu_3^{\beta_1} & = & \mu_3 \cdot \mu_1 \\ \delta_3^{\beta_3} & = & \mu_8^{\beta_3} \cdot \mu_9^{\beta_3} & = & \mu_9 \cdot \mu_7 \cdot \mu_2 \cdot \mu_7^{-1} \end{array}$$

Therefore, by Remark 4.12(2) and Proposition 4.6(a), we have

$$\begin{array}{rcl} \Delta_1 & = & (\tilde{\mu}_3)_1 + (\tilde{\mu}_1)_3 \\ \Delta_3 & = & (\tilde{\mu}_9)_1 + (\tilde{\mu}_7)_2 + (\tilde{\mu}_2)_2 + (\tilde{\mu}_7^{-1})_3 \quad = \quad (\tilde{\mu}_9)_1 + (\tilde{\mu}_2)_2 + (\tilde{\mu}_7)_3. \end{array}$$

The Picard-Lefschetz transformation $\Psi_{\nabla(\gamma_1)}$ of the vanishing path $\delta_3^{\beta_3}$ is

$$\Psi_{\nabla(\gamma_1)}(\delta_3^{\beta_3}) = \delta_3^{\beta_3 \nabla(\gamma_1)} = \mu_9 \cdot \mu_7 \cdot \mu_3 \cdot \mu_1^{-1} \cdot \mu_2 \cdot \mu_1 \cdot \mu_3^{-1} \cdot \mu_7^{-1}.$$

Finally, by Remark 4.12(2) and Proposition 4.6(a), we have

$$\begin{array}{rcl} h_{\gamma_1}(\Delta_3) & = & (\tilde{\mu}_9)_1 + (\tilde{\mu}_7)_2 + (\tilde{\mu}_3)_2 + (\tilde{\mu}_1^{-1})_2 + (\tilde{\mu}_2)_2 + (\tilde{\mu}_1)_3 + (\tilde{\mu}_3^{-1})_1 + (\tilde{\mu}_7^{-1})_3 \\ & = & (\tilde{\mu}_9)_1 + (\tilde{\mu}_2)_2 + (\tilde{\mu}_1)_3 + (\tilde{\mu}_3)_1 + (\tilde{\mu}_7)_3 \\ & = & [(\tilde{\mu}_9)_1 + (\tilde{\mu}_2)_2 - (\tilde{\mu}_7)_1] + [-(\tilde{\mu}_1)_1 + (\tilde{\mu}_3)_1] = \Delta_3 + \Delta_1, \end{array}$$

and hence $(\Delta_1, \Delta_3) = 1$. ■

Remark 5.5. Note that the matrices in (5.10) have been decomposed into four blocks. The diagonal ones can be divided as

$$\left[\begin{array}{c|c} 0 & 0 \\ \hline 0 & 0 \end{array}\right] \text{ and } \left[\begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 1 & 1 \\ 0 & -1 & 0 & 1 \\ 0 & -1 & -1 & 0 \end{array}\right].$$

representing the intersection matrices of the germ $f^{\pm}$ in the singular points with singularities $\mathbb{A}_1^{\pm}, \mathbb{A}_1^0$ and $\mathbb{A}_3^0$ respectively.

We have (see Figures 7 and 8) $\gamma_0^{\pm} = \gamma_6 \cdot \gamma_5 \cdot \gamma_4 \cdot \gamma_3$ and $\gamma_1^{\pm} = \gamma_2 \cdot \gamma_1$ then

$$\begin{array}{rcl} (h_{\gamma_0^{\pm}})_* & = & (h_{\gamma_3})_* \circ (h_{\gamma_4})_* \circ (h_{\gamma_5})_* \circ (h_{\gamma_6})_* \text{ and} \\ (h_{\gamma_1^{\pm}})_* & = & (h_{\gamma_1})_* \circ (h_{\gamma_2})_*. \end{array} \tag{5.11}$$

By Picard-Lefschetz Theorem, the intersection matrices $\mathbb{I}_{f^{\pm}}$ give us the Picard-Lefschetz operators $(h_{\gamma_i})_*, i = 1, \ldots, 6$, in the bases $\mathcal{B}^{\pm}$. Finally, by (5.11) and Notation 5.2, we have

$$H_0^+ = \left[\begin{array}{cc|cc|cc} 1 & 0 & 0 & \multicolumn{1}{c}{0} & 0 & 0 \\ 0 & 1 & 0 & \multicolumn{1}{c}{0} & 0 & 0 \\ \hline -1 & -1 & 1 & 0 & 0 & 0 \\ \cline{3-6} 0 & 0 & 0 & 0 & -1 & 0 \\ 0 & -1 & 0 & 0 & 0 & -1 \\ 1 & 1 & 0 & 1 & 1 & 1 \end{array}\right] \text{ and } H_1^+ = \left[\begin{array}{c|c|cccc} 1 & 0 & 1 & -1 & -1 & -1 \\ \cline{1-2} 0 & 1 & 1 & 0 & 0 & -1 \\ \hline \multicolumn{1}{c}{0} & 0 & 1 & 0 & 0 & 0 \\ \multicolumn{1}{c}{0} & 0 & 0 & 1 & 0 & 0 \\ \multicolumn{1}{c}{0} & 0 & 0 & 0 & 1 & 0 \\ \multicolumn{1}{c}{0} & 0 & 0 & 0 & 0 & 1 \end{array}\right] \tag{5.12}$$

in the basis $\mathcal{B}^+$ and

$$H_0^- = \left[\begin{array}{cc|cccc} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ \hline \text{-1} & 0 & 1 & \multicolumn{1}{c|}{0} & 0 & 0 \\ \cline{3-6} 1 & 1 & 0 & \multicolumn{1}{c|}{0} & \text{-1} & 0 \\ 0 & \text{-1} & 0 & \multicolumn{1}{c|}{0} & 0 & \text{-1} \\ 0 & \text{-1} & 0 & \multicolumn{1}{c|}{1} & 1 & 1 \end{array}\right] \text{ and } H_1^- = \left[\begin{array}{cc|cccc} \multicolumn{1}{c|}{1} & 0 & 1 & \text{-1} & 0 & 0 \\ \cline{1-2} \multicolumn{1}{c|}{0} & 1 & 0 & 1 & 2 & 1 \\ \hline 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{array}\right] \tag{5.13}$$

in the basis $\mathcal{B}^-$.

Remark 5.6. Let $f : \mathbb{C}^n \to \mathbb{C}$ be a polynomial function with isolated singularities (no further hypotheses). As we said in Section 1, given a geometric basis $(\gamma_1, \ldots, \gamma_{\#B_f})$ of $\pi_1(\mathbb{C} \setminus B_f; \star)$, we obtain a decomposition of $H_j(V_\star(f))$. To do this let $F_{i,\alpha} \subset V_\star(f)$ $(1 \leq i \leq \#B_f)$ be Milnor fibers of affine singularities for $1 \leq \alpha \leq \alpha_i$ and Milnor fibers at infinity for $\alpha_i + 1 \leq \alpha \leq \alpha'_i$. Then for $j > 0$:

$$H_j(V_\star(f)) \cong \bigoplus_{i=1}^{\#B_f} \left(\bigoplus_{\alpha=1}^{\alpha'_i} (v_i)_j \left(H_j \left(F_{i,\alpha}, \partial F_{i,\alpha} \right) \right) \right) \tag{5.14}$$

where $(v_i)_j$ is the composition of the variation and inclusion operators

$$\begin{array}{cccccc} (v_i)_j : & H_j(F_{i,\alpha}, \partial F_{i,\alpha}) & \xrightarrow{\text{var}} & H_j(F_{i,\alpha}) & \overset{i}{\hookrightarrow} & H_j(V_\star(f)) \\ & a & \mapsto & a - (h_{\gamma_i})_*(a) & \mapsto & a - (h_{\gamma_i})_*(a). \end{array}$$

Using this decomposition $(h_{\gamma_i})_*$ can be written as

$$\begin{bmatrix} I_1 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ 0 & I_2 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & & \vdots & \vdots & \vdots & & \vdots \\ *_{i,1} & *_{i,2} & \cdots & *_{i,i-1} & h_i & *_{i,i+1} & \cdots & *_{i,\#B_f} \\ \vdots & \vdots & & \vdots & \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & I_{\#B_f} \end{bmatrix}, \; h_i = \begin{bmatrix} h_{i,1} & 0 & \cdots & 0 \\ 0 & h_{i,2} & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & h_{i,\alpha'_i} \end{bmatrix},$$

where I_j is the identity matrix, h_i is the restriction of $(h_{\gamma_i})_*$ to the subspace $\bigoplus_{1 \leq \alpha \leq \alpha'_i} (v_i)_j (H_j(F_{i,\alpha}, \partial F_{i,\alpha}))$ (respecting the sum decomposition) and $h_{i,\alpha}$, for $1 \leq \alpha \leq \alpha'_i$, is the restriction of $(h_{\gamma_i})_*$ to $(v_i)_j(H_j(F_{i,\alpha}, \partial F_{i,\alpha}))$ (see [12, Lemma 2.4], [23, Theorem 3.1] or [24, Theorem 1.4]). In particular $h_{i,\alpha}$ and $*_{i,s}$ are, respectively, the local blocks and the global blocks that we mentioned in Section 1.

The distinguished bases $(\gamma_1, \ldots, \gamma_6)$ in Figures 7 and 8 define a special geometric basis as we considered in Section 1. Then associated distinguished bases of cycles $\mathcal{B}^\pm$ give the decomposition (5.14). We have shown the aforementioned submatrices $I_j, *_{i,s}, h_i$ and $h_{i,\alpha}$ in (5.12) and (5.13).

5.3. **The polynomials $f^\pm$ are not topologically equivalent.** As we mentioned in Section 5.1, if $f^\pm$ were topologically equivalent then there should exist P satisfying (5.5). In Section 5.2 we have computed the matrices $H_0^\pm$ and $H_1^\pm$ shown in (5.12) and (5.13). The problem becomes a linear system with 72 equations and 36 variables. The system of solutions is

$$P(a,b) := \begin{bmatrix} 0 & 0 & a & a & 0 & a \\ 0 & 0 & -a & -a & 0 & -a \\ 0 & 0 & a+b & a+b & 0 & a+b \\ 0 & 0 & b & b & 0 & b \\ 0 & 0 & -b & -b & 0 & -b \\ 0 & 0 & a+b & a+b & 0 & a+b \end{bmatrix}$$

with $a, b \in \mathbb{C}$ (solved with `Maple`). Since $P(a, b)$ is a singular matrix, the system (5.5) has no solution and hence the polynomials $f^{\pm}$ are not topologically equivalent.

6. Proof of Theorem 4.10

This last section is dedicated to proving Theorem 4.10. Hence we should assume that $f \in \mathbb{C}[x, y]$ is a monic polynomial of degree N in the variable y and satisfying Hypothesis 4.8.

Lemma 6.1. *It is enough to prove Theorem 4.10 for* $j = 1$.

Proof. Let us assume that Theorem 4.10 is true for $j = 1$. By Lemma 2.12(a) and Theorem 4.10(1) (case $j = 1$) we have $\nabla_{\star,\mathfrak{D}}(\gamma_i) = (\alpha_j^{-1}\beta_i)^{-1}\sigma_j(\alpha_j^{-1}\beta_i)$ and thus Theorem 4.10(1) is true for $j > 1$.

By Lemma 2.12(b) we have $\mu_j^{(\alpha_j^{-1}\beta_i)} = \mu_1^{\beta_i}$ and $\mu_{j+1}^{(\alpha_j^{-1}\beta_i)} = \mu_2^{\beta_i}$ and hence, since Theorem 4.10(2) it is true for $j = 1$, it is also true for $j > 1$. □

6.1. **Discriminant properties of a Morse polynomial.**

Lemma 6.2. *Let* $t_o \in T \setminus \mathcal{T}_{Sing}$ *and let* $x^{t_o} \in \mathbf{x}^{t_o}$ *be a ramification point of* (4.1). *In a neighborhood of* x^{t_o} *the function* $f(x, y) - t_o$ *is the product of* $N-1$ *Weierstrass polynomials in the variable* y *centered in the* $N-1$ *preimages of the point* x^{t_o}. *Also note that all those polynomials have degree 1 but one which has degree 2 and has either non-degenerate singularities if* $(t_o, x^t) = (t_i, x_i)$, *for some* i, *or is smooth if* $(t_o, x^{t_o}) \neq (t_i, x_i)$.

Proof. Let $\bar{y}_j \in \mathbb{C}$, $j = 1, \ldots, r$, be a root of $f(x^{t_o}, y) - t_o$. Then $(x^{t_o}, \bar{y}_j)$, for $j = 1, \ldots, r$, are all preimages of x^{t_o}. Since x^{t_o} is a ramification point, $r \leq N - 1$. If $r < N - 1$, then by Corollary 3.3 the discriminant germ $(\mathfrak{D}_f, (t_o, x^{t_o}))$ is singular and hence $t_o \in \mathcal{T}_{Sing}$ which is a contradiction.

Therefore $r = N - 1$ and hence there exists a root $\bar{y}_1$ of order 2, whereas $\bar{y}_j$, for $j = 2, \ldots, N-1$, are simple roots. By Hensel's Lemma $f(x, y) - t_o$ is, locally, the product of $N - 1$ Weierstrass polynomials $P_j(x, y)$ in the variable y centered in $(x^{t_o}, \bar{y}_j)$ and whose degree is the multiplicity of $\bar{y}_j$. Thus $P_j(x, y)$, $j = 2, \ldots, N-1$, have degree 1 and $P_1(x, y)$ has degree 2 where:

- If $(t_o, x^{t_o}) = (t_i, x_i)$, for some i, then y_i is root of $f(x^{t_i}, y) - t_i$, thus $\bar{y}_1 = y_i$ and $P_1(x, y)$ has a non-degenerate singularity at (x_i, y_i).
- If $t_o \notin \mathcal{T}$, then the fiber $V_{t_o}(f)$ is smooth. Finally, if $t_o = t_i$ but $x^{t_i} \neq x_i$, then the point $(x^{t_i}, \bar{y}_1)$ is not singular. In either case, $P_1(x, y)$ is smooth.

□

Corollary 6.3. *In a neighborhood of* $t_o \in T \setminus \mathcal{T}_{Sing}$ *the function* $d_f(t, x)$ *is:*

(a) $a\prod_{\alpha=1}^{k} \ell_\alpha(x, t)$, *if* $t_o \notin f(P)$.
(b) $a\ q(x, t)\prod_{\alpha=2}^{k-1} \ell_\alpha(x, t)$, *if* $t_o = t_i$, *for some* i.
where

$$\ell_\alpha(x, t) := (x - x_\alpha^{t_o}) + c_\alpha(t)(t - t_o), q(x, t) := (x - x_i)^2 + b_1(t)(x - x_i) + c_1(t)(t - t_o)$$

for $x_\alpha^{t_o} \in \mathbf{x}^{t_o}$, $a \in \mathbb{C}^*, b_1, c_\alpha \in \mathbb{C}[t]$, $b_1(t_o) = 0$ *and* $c_\alpha(t_o) \neq 0, \alpha = 1, ..., k$,

Proof. By Lemma 6.2 and Lemma 3.2 the function $d_f(\tilde{t} + t_o, \tilde{x} + x_\alpha^{t_o})$ is:

- a polynomial $\tilde{x}$-regular of degree $0 + N - (N - 1) = 1$ and $\tilde{t}$-regular of degree $N - (N - 1) = 1$, if $(t_o, x_\alpha^{t_o}) \neq (t_i, x_i)$.
- a polynomial $\tilde{x}$-regular of degree $1 + N - (N - 1) = 2$ and $\tilde{t}$-regular of degree $N - (N - 1) = 1$, if $(t_o, x_\alpha^{t_o}) = (t_i, x_i)$, for some i.

The result follows by uniqueness of Weierstrass Theorem, Hensel's Lemma and the fact that $d_f(t,x)$ as polynomial in the variable x has degree k. $\square$

Corollary 6.4. *The image of each member of a geometric basis by the classical monodromy* $m_t : \pi_1(X \setminus \mathbf{x}^t; *) \to \Sigma_N, t \in T \setminus \mathcal{T}, * \in \partial X$, *associated with* (4.1) *is a transposition.*

Proof. Since $t \in T \setminus \mathcal{T}$, Lemma 6.2 gives us the existence of a smooth Weierstrass polynomial of degree 2, say $P(x,y)$. If we lift the path $x^t + \rho\, e^{2\pi u}, u \in [0,1]$, for a sufficiently small ρ, we obtain, again by Lemma 6.2, a transposition given by the move of the two roots of $P(x^t + \rho, y) = 0$. So the corollary follows. $\square$

6.2. **Braid monodromy.** In this section we prove Theorem 4.10(1)

Notation 6.5. To simplify notation, we will denote $\tau_{\mathbf{x}^t,\mathfrak{O}(\psi)}, t \in \mathbb{C}$, $\tau(\mathfrak{O}(\psi))$ and $\nabla_{\star,\mathfrak{O}(\psi)}$ simply by $\tau_{t,\psi}$, $\tau(\psi)$ and $\nabla_{t,\psi}$.

Proposition 6.6. *Let S be a circle with support in $T \setminus \mathcal{T}$, based at $\diamond \in \mathbb{C}$ and centered at $t_i \in f(P)$. If the radius of S, $\xi := ||t_i - \diamond||$, is sufficiently small, then for almost all $\psi \in (0,\pi)$, $\nabla_{\diamond,\psi}(S) = \sigma_j$, where $1 \leq j \leq k$ and j depends of ψ.*

Proof. Let $\theta := (\bar{\pi}|_{\mathfrak{D}_f})_*(S)$. The braid θ is the homotopy class of

$$\{(t_i + \xi e^{2\pi\sqrt{-1}u}, x) \,|\, x \in \mathbf{x}^{t_i + \xi e^{2\pi\sqrt{-1}u}}, u \in [0,1]\}$$

By Corollary 6.3(b) the set $\mathbf{x}^{t_i}$ has $k-1$ points. Almost every $\psi \in (0,\pi)$ has the property that all lines with slope $\tan(\psi)$ have no more than one point in $\mathbf{x}^{t_i}$. Let ψ be one of such angles. Let also be $j \in \{1,\ldots,k-1\}$ such that $x_i = x_j^{t_i} \in \mathbf{x}^{t_i}(\psi)$.

By Corollary 6.3 (see Figure 9), for a sufficiently small ξ, the points of the list $\mathbf{x}^{t_i + \xi e^{2\pi\sqrt{-1}u}}(\psi)$ satisfy

$$x_j^{t_i + \xi e^{2\pi\sqrt{-1}u}} \xrightarrow{\xi \to 0} \begin{cases} x_j^{t_i} & \text{for } j < j \\ x_j^{t_i} = x_i & \text{for } j = j, j+1 \\ x_{j-1}^{t_i} & \text{for } j > j+1 \end{cases}$$

and the local equation of $\mathfrak{D}_f$ at (t_i, x_i) is $(x - x_i)^2 + b_1(t)(x - x_i) + c_1(t)(t - t_i)$, $b_1(t_i) = 0, c_1(t_i) \neq 0$. Thus the braid $\nabla_{\diamond,\psi}(S) = \theta(\psi) = \tau_{\diamond,\psi}\, \theta\, \tau_{\diamond,\psi}^{-1}$ is equal to $\sigma_j \in \mathbb{B}_k$ by definition of $\tau_{\diamond,\psi}$ (see Notations 2.7 and 6.5). $\square$

Figure 9.

Let γ_i be an element of the distinguished basis of the Theorem 4.10 and let γ be a meridian homotopic to γ_i as in Definition 4.9 such that $\operatorname{Supp}\gamma \subset T \setminus \mathcal{T}$. According to Definition 2.1 the following elements are associated with γ

$$(t_\gamma(= t_i), t'_\gamma(=: \diamond), r_\gamma(=: r), S_\gamma(=: S), D_\gamma(=: D)). \tag{6.1}$$

Let $\psi \in (0, \pi)$. We need the following technical hypothesis:

Hypothesis 6.7. Proposition 6.6 is satisfied for the element S of γ and ψ.

Notation 6.8. We denote $\theta := (\tilde{\pi}|_{\mathfrak{D}_f})_*(S)$ and $\beta := (\tilde{\pi}|_{\mathfrak{D}_f})_*(r^{-1})$ the braids in $\mathbb{B}(\mathbf{x}^\diamond, \mathbf{x}^\diamond)$ and $\mathbb{B}(\mathbf{x}^\diamond, \mathbf{x}^\star)$, respectively.

By the first part of Proposition 2.8(a) and since braid monodromy is a homotopy invariant we have

$$\nabla_{\star,\mathfrak{D}}(\gamma_i) = \nabla_{\star,\mathfrak{D}}(\gamma) = \beta^{-1}(\mathfrak{D})\theta(\mathfrak{D})\beta(\mathfrak{D}) \tag{6.2}$$

and, by Proposition 6.6,

$$\nabla_{\star,\psi}(\gamma_i) = \nabla_{\star,\psi}(\gamma) = \beta(\psi)^{-1}\theta(\psi)\beta(\psi), \quad \text{where } \theta(\psi) = \sigma_j. \tag{6.3}$$

By the second part of Proposition 2.8(b) the braid $\theta(\mathfrak{D})$ is conjugated to $\theta(\psi) = \sigma_j$. Then Theorem 4.10(1) follows from Lemma 2.12(a).

6.3. **The vanishing cycle of a critical value.** In this section we prove Theorem 4.10(2.a) and (2.b.i). To do this we will first prove it in the special case when γ_i is in fact γ and $\mathfrak{D}$ is the base set of braids $\mathfrak{D}(\psi)$ with γ and ψ as in Section 6.2. This is done in the next three subsections. Finally, in the last subsection, we prove the theorem in the general case.

6.3.1. *Construction of the vanishing cycle.* Let us parametrize the segment $[\diamond, t_i]$ as $\lambda(u) := (1-u)(\diamond - t_i) + t_i, u \in [0,1]$. Let s be the segment in $\{t = \diamond\} \times \mathbb{C}$ between the points $x_j^\diamond$ and $x_{j+1}^\diamond$ of $\mathbf{x}^\diamond(\psi)$. By Corollary 6.3, while u moves towards 1, the points $x_j^{\lambda(u)}, x_{j+1}^{\lambda(u)} \in \mathbf{x}^{\lambda(u)}(\psi)$ converge to x_i then the path s degenerates into a point (t_i, x_i) as we move towards t_i on the interval $[\diamond, t_i]$ (see Figure 10).

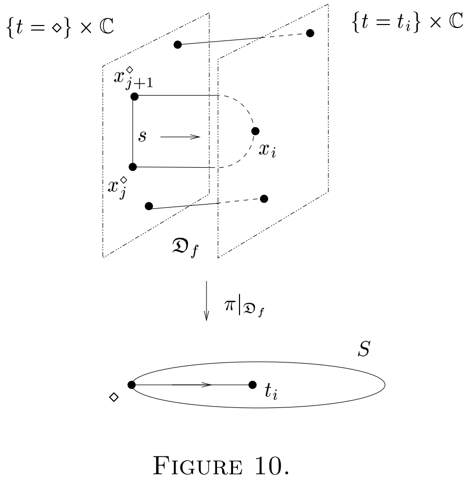

FIGURE 10.

For every $\lambda(u) \in [\diamond, t_i)$ let $H_{\tau_{\lambda(u),\psi}}$ be an $(\mathbf{x}, \mathbf{x}^{\lambda(u)})$-special isotopy associated with $\tau_{\lambda(u),\psi}$, which is the identity in $\mathbb{C} \setminus \operatorname{Int}(X)$ such that the map

$$\begin{array}{rccc} H: & [0,1) \times (\mathbb{C} \times [0,1]) & \longrightarrow & \mathbb{C} \\ & (u, x, v) & \mapsto & H_{\tau_{\lambda(u),\psi}}(x, v) \end{array} \tag{6.4}$$

is continuous in the variable u. By continuity we can extend H to $[0,1] \times (\mathbb{C} \times [0,1])$.

We define a topological cylinder $\mathfrak{C}$ with $\mathfrak{C}_u := H\left(u, \mathbb{D}_1\left(\frac{2j+1}{2}\right), 1\right), 0 \leq u \leq 1$, its fibers, where j is the element given by Proposition 6.6 for the fixed ψ. The cylinder $\mathfrak{C}$ satisfies that

$$x_j^{\lambda(u)}, x_{j+1}^{\lambda(u)} \in \operatorname{Int}(\mathfrak{C}_u),\ \ \mathfrak{C}_u \cap (\mathbf{x}^{\lambda(u)} \setminus \{x_j^{\lambda(u)}, x_{j+1}^{\lambda(u)}\}) = \emptyset, \quad 0 \leq u < 1,$$

$$x_i \in \operatorname{Int}(\mathfrak{C}_1) \text{ and } \mathfrak{C}_1 \cap (\mathbf{x}^{t_i} \setminus \{x_i\}) = \emptyset,$$

By Lemma 6.2 the set $\phi_{f,x}^{-1}(\{t = \lambda(u)\} \times \mathfrak{C}_u)$ has $N-1$ components where $N-2$ of them are diffeomorphic to a topological disk and the remaining one is diffeomorphic to the cylinder $\mathbb{S}^1 \times [-1,1]$ for $0 \leq u < 1$, and to two disks intersecting at the point (x_i, y_i) for $u = 1$.

Let $\mathbb{S}(0)$ be the preimage of s in $\phi_{f,x}^{-1}(\{t = \diamond\} \times \mathfrak{C}_0)$. Note that $\mathbb{S}(0)$ is a closed path according to (4.1). Analogously, one obtains a family of closed paths $\mathbb{S}(u)$, $0 < u < 1$ as the path s is moved along the segment $[\diamond, t_i]$. We denote also $\mathbb{S}(1) := \{(x_i, y_i)\}$. Hence there is a 2-dimensional closed topological disk $\mathbb{D}$ satisfying (see Figure 11):

i. $\mathbb{S}(u) = \mathbb{D} \cap V_{\lambda(u)}(f)$, $0 \leq u < 1$, is diffeomorphic to the circle.
ii. $\mathbb{S}(1) = \mathbb{D} \cap V_{t_i}(f) = \{(x_i, y_i)\}$.
iii. $\mathbb{D} = \bigcup \mathbb{S}(u)$.

Therefore $\mathbb{S}(0)$ defines a vanishing cycle in $V_\diamond(f)$.

Figure 11.

6.3.2. *Representation of the vanishing cycle in* $H_1(V_\diamond(f))$. Since $\operatorname{Supp}(\gamma) \subset T \setminus \mathcal{T}$ we can use the topological model described in Section 4.1 to give a representation of $\mathbb{S}(0)$ in $H_1(V_\diamond(f))$.

Let us consider the geometric basis $(\mu_1, ..., \mu_k)$ as in Example 2.3 associated with the disk X fixed above and the set $\mathbf{x} = \{1, 2, ..., k\}$ (by (3) in Section 4 $\mathbf{x} \subset X$). By Artin Theorem [5] the Hurwitz move $\Psi_{\tau_{\diamond,\psi}}$ transforms this geometric basis into the geometric basis $(\mu_1^{\tau_{\diamond,\psi}}, \ldots, \mu_k^{\tau_{\diamond,\psi}})$ of $\pi_1(X \setminus \mathbf{x}^\diamond; *)$.

For the sake of simplicity we will skip the subindices $\diamond, \psi$ from $\tau_{\diamond,\psi}$. By Definition 2.1 the elements associated with μ_n^τ are

$$(x_{\mu_n^\tau}(= x_n^\diamond), x'_{\mu_n^\tau}, r_{\mu_n^\tau}, S_{\mu_n^\tau}, D_{\mu_n^\tau}). \tag{6.5}$$

By construction of the vanishing cycle, the classical monodromy $m_\diamond$ satisfies

$$m_\diamond(\mu_j^\tau) = m_\diamond(\mu_{j+1}^\tau). \tag{6.6}$$

Moreover, by Corollary 6.4 $m_\diamond(\mu_j^\tau)$ is a transposition, say $(a, b), a, b \in \{1, \ldots, N\}$, $a \neq b$.

Let $\delta := \mu_{j+1} \cdot \mu_j$ be a path in $X \setminus \mathbf{x}$. We want to lift $\Psi_\tau(\delta) = \delta^\tau = \mu^\tau_{j+1} \cdot \mu^\tau_j$ by means of the projection $\pi|_{V_\diamond(f)}$ (4.1). This lifting is a union of N closed paths in the fiber $V_\diamond(f)$:

$$
\begin{aligned}
(\delta^\tau)_l &= (\mu^\tau_{j+1})_l \cdot (\mu^\tau_j)_l \text{ with } l \in \{1, \dots, N\}, l \neq a, b,\\
(\delta^\tau)_a &= (\mu^\tau_{j+1})_a \cdot (\mu^\tau_j)_b \text{ and } (\delta^\tau)_b = (\mu^\tau_{j+1})_b \cdot (\mu^\tau_j)_a.
\end{aligned}
$$

The following lemma allows us to find paths that are homologous to the vanishing cycle $\mathbb{S}(0)$ (Section 6.3.1). These paths will let us transport easily $\mathbb{S}(0)$ to the fiber $V_\star(f)$.

Lemma 6.9. *The liftings $(\delta^\tau)_l, l = 1, \dots, N$, in $V_\diamond(f)$ are homologous -up to sign- to the vanishing cycle $\mathbb{S}(0)$ if $l = a, b$ and to the zero cycle if $l \neq a, b$. Also in homology $(\delta^\tau)_b = -(\delta^\tau)_a$.*

Proof. Let us deform the path s continuously in

$$\{t = \diamond\} \times (X \setminus \bigcup_{n \neq j,\, j+1} x^\diamond_n)$$

as shown in Figure 12 (a), so as to turn it into a path with support

$$[x^\diamond_j, x'_{\mu^\tau_j}] \cup \operatorname{Supp}(r^{-1}_{\mu^\tau_j}) \cup \operatorname{Supp}(r_{\mu^\tau_{j+1}}) \cup [x'_{\mu^\tau_{j+1}}, x^\diamond_{j+1}],$$

where these paths are the ones associated with μ^τ_j (see (6.5)). The support of δ^τ is

$$\operatorname{Supp}(S_{\mu^\tau_j}) \cup \operatorname{Supp}(r^{-1}_{\mu^\tau_j}) \cup \operatorname{Supp}(r_{\mu^\tau_{j+1}}) \cup \operatorname{Supp}(S_{\mu^\tau_{j+1}}).$$

Therefore the cycles $\mathbb{S}(0)$, $(\delta^\tau)_a$ and $(\delta^\tau)_b$ in $V_\diamond(f)$ (Figure 12 (b)) are homologous up to orientation.

FIGURE 12. (a) Deformation of s. (b) Paths $\mathbb{S}(0)$ and $(\delta^\tau)_a$.

By Proposition 4.6(c) and (6.6) the N paths $(\delta^\tau)_l$ are elements in $Z_1(\mathfrak{K})$ and hence, by Proposition 4.6(a) as cycles in $H_1(V_\diamond(f))$ (see (4.7)) they look like:

$$
\begin{aligned}
&(\delta^\tau)_l = (\mu^\tau_{j+1})_l + (\mu^\tau_j)_l = \ 0 \text{ with } l \in \{1, \dots, N\}, l \neq a, b,\\
&(\delta^\tau)_a = (\mu^\tau_{j+1})_a + (\mu^\tau_j)_b \text{ and}\\
&(\delta^\tau)_b = (\mu^\tau_{j+1})_b + (\mu^\tau_j)_a = -(\mu^\tau_{j+1})_a - (\mu^\tau_j)_b = -(\delta^\tau)_a.
\end{aligned}
$$

□

6.3.3. *Representation of the vanishing cycle in $H_1(V_\star(f))$.* In this subsection we will compute the homological class of the local vanishing cycle $\mathbb{S}(0)$ in the global fiber $H_1(V_\star(f))$. In order to do so we will use Lemma 6.9 which allows us to work with $(\delta^\tau)_a$ or $(\delta^\tau)_b$ and move them from $V_\diamond(f)$ to $V_\star(f)$ by the diffeomorphism $h_{r^{-1}}$ given by lifting the path r^{-1}. Let us first study the diffeomorphism $h_{r^{-1}}$ more closely.

The diffeomorphism $h_{r^{-1}}$. Let $\beta\in\mathbb{B}(\mathbf{x}^\diamond,\mathbf{x}^\star)$ the braid defined by r^{-1} as in Notation 6.8 and H_β a $(\mathbf{x}^\diamond,\mathbf{x}^\star)$-special isotopy associated to β which is the identity in $\mathbb{C}\setminus\operatorname{Int}(X)$. Then we can define

$$\begin{array}{rccc}\bar{H}: & \{\diamond\}\times\mathbb{C}\times[0,1] & \longrightarrow & \operatorname{Supp}(r^{-1})\times\mathbb{C}. \\ & (\diamond,x,u) & \mapsto & (r^{-1}(u),H_\beta(x,u))\end{array}$$

Let $\mathcal{X}:=\{(r^{-1}(u),x)\in T\times X\mid u\in[0,1],x\notin\mathbf{x}^{r^{-1}(u)}\}$ and $\mathcal{R}:=\phi_{f,x}^{-1}(\mathcal{X})$ with fibers

$$\mathcal{X}_u:=\mathcal{X}\cap(\{r^{-1}(u)\}\times\mathbb{C})\text{ and }\mathcal{R}_u:=\phi_{f,x}^{-1}(\mathcal{X}_u),u\in[0,1]. \tag{6.7}$$

Then we have the following N-folded covering maps

$$\phi_{f,x}|:\mathcal{R}\longrightarrow\mathcal{X}\quad\text{and}\quad(\phi_{f,x}|,1):\mathcal{R}_0\times[0,1]\longrightarrow\mathcal{X}_0\times[0,1]$$

and a diffeomorphism between the base spaces $\bar{H}|:\mathcal{X}_0\times[0,1]\to\mathcal{X}$. Let $\tilde{*}\in\mathcal{R}_0$ be such that $\phi_{f,x}(\tilde{*})=(\diamond,*)\in\mathcal{X}_0$. Since $r^{-1}(u)$ $(u\in[0,1])$ are all regular values of f and $\pi|_{\mathfrak{D}_f}$, one has $\pi_1(\mathcal{X};*)\simeq\pi_1(\mathcal{X}_0;*)$ and $\pi_1(\mathcal{R};\tilde{*})\simeq\pi_1(\mathcal{R}_0;\tilde{*})$. Therefore, by Lifting Theorem, the diffeomorphism between the base spaces gives us a unique diffeomorphism Γ between the covering spaces such as $\Gamma(\tilde{*},0)=\tilde{*}$ and such that the following diagram is commutative

$$\begin{tikzcd}\mathcal{R}_0\times[0,1] \arrow[r, "\Gamma"] \arrow[d, "{(\phi_{f,x},1)}"'] \arrow[dr, phantom, "\circlearrowleft"] & \mathcal{R} \arrow[d, "\phi_{f,x}"] \\ \mathcal{X}_0\times[0,1] \arrow[r, "\bar{H}|"] & \mathcal{X}.\end{tikzcd} \tag{6.8}$$

By restriction we have the following families of diffeomorphisms

$$\begin{array}{rccc}\bar{H}_u: & \{\diamond\}\times\mathbb{C} & \longrightarrow & \mathbb{C} \\ & (\diamond,x) & \mapsto & (r^{-1}(u),H_\beta(x,u)) \\ \Gamma_u: & \mathcal{R}_0 & \longrightarrow & \mathcal{R}_u \\ & (x,y) & \mapsto & \Gamma(x,y,u).\end{array} \tag{6.9}$$

Each $\bar{H}_u$ is such that $\bar{H}_u(\mathcal{X}_0)=\mathcal{X}_u$ and each Γ_u is such that $f(\Gamma_u(\bullet))=r^{-1}(u)$ and it can be extended continuously to $\phi_{f,x}^{-1}(\{t=\diamond\}\times\mathbf{x}^\diamond)$. Finally we define the diffeomorphism $h_{r^{-1}}:=\Gamma_1$. Note that, by (6.8), the following is a commutative diagram:

$$\begin{tikzcd}\mathcal{R}_0 \arrow[r, "h_{r^{-1}}|"] \arrow[d, "\phi_{f,x}"'] \arrow[dr, phantom, "\circlearrowleft"] & \mathcal{R}_1 \arrow[d, "\phi_{f,x}"] \\ \mathcal{X}_0 \arrow[r, "\bar{H}_1|"] & \mathcal{X}_1.\end{tikzcd} \tag{6.10}$$

Moreover, using a theorem of continuity of the roots for $f(x,y)=r^{-1}(u)$, with $x\in\mathbb{C}\setminus\operatorname{Int}(\mathcal{X}_0)$ and $u\in[0,1]$, and since $\bar{H}_u$ is the identity on the second variable in $\{\diamond\}\times\mathbb{C}\setminus\operatorname{Int}(\mathcal{X}_0)$, this diagram can be extended to $V_\diamond(f)$.

Remark 6.10. Let $H_{\beta^{-1}}(\bullet,u):=H_\beta^{-1}(\bullet,u)$ be an $(\mathbf{x}^\star,\mathbf{x}^\diamond)$-special isotopy associated with β^{-1}. Analogously as above, one can construct the diffeomorphism h_r and the commutative diagram:

$$\begin{tikzcd}\mathcal{R}_1 \arrow[r, "h_r|"] \arrow[d, "\phi_{f,x}"'] \arrow[dr, phantom, "\circlearrowleft"] & \mathcal{R}_0 \arrow[d, "\phi_{f,x}"] \\ \mathcal{X}_1 \arrow[r, "\bar{H}_1^{-1}|"] & \mathcal{X}_0.\end{tikzcd} \tag{6.11}$$

Moving the paths $(\delta^{\tau})_a$ *and* $(\delta^{\tau})_b$. By Artin Theorem $(\mu_1^{\tau\beta},\dots,\mu_k^{\tau\beta})$ is a geometric basis of $\pi_1(X\setminus \mathbf{x}^{\star};*)$. Let $\mathcal{Y}_{r^{-1}}$ be the braid in N strings defined by the equation $f(*,y)=r^{-1}(u), u\in[0,1]$. If we consider $\mathcal{Y}_{r^{-1}}$ as a permutation, by (6.6), we have

$$m_\star(\mu_j^{\tau\beta}) = m_\star(\mu_{j+1}^{\tau\beta}) = (a^{\mathcal{Y}_{r^{-1}}}, b^{\mathcal{Y}_{r^{-1}}}) =: (\bar a,\bar b). \tag{6.12}$$

Lemma 6.11. *Let* $\bar l := l^{\mathcal{Y}_{r^{-1}}}$, *with* $l=1,\dots,N$. *The liftings* $(\delta^{\tau\beta})_{\bar l}$ *in* $V_\star(f)$ *are homologous to the vanishing cycle* $(h_{r^{-1}})_*(\mathbb{S}(0))$ *if* $\bar l=\bar a,\bar b$ *and are the zero cycle if* $\bar l\neq\bar a,\bar b$. *Moreover,* $(\delta^{\tau\beta})_{\bar a} = -(\delta^{\tau\beta})_{\bar b} = (\mu_{j+1}^{\tau\beta})_{\bar a} + (\mu_j^{\tau\beta})_{\bar b}$.

Proof. By the commutative diagram (6.10) and by equation (6.12) we have the following equalities in homotopy

$$\begin{array}{rclcll}
h_{r^{-1}}((\delta^\tau)_l) &=& (\delta^{\tau\beta})_{\bar l} &=& (\mu_{j+1}^{\tau\beta})_{\bar l}\cdot(\mu_j^{\tau\beta})_{\bar l} & \text{for } \bar l\neq \bar a,\bar b,\\
h_{r^{-1}}((\delta^\tau)_a) &=& (\delta^{\tau\beta})_{\bar a} &=& (\mu_{j+1}^{\tau\beta})_{\bar a}\cdot(\mu_j^{\tau\beta})_{\bar b} & \text{and}\\
h_{r^{-1}}((\delta^\tau)_b) &=& (\delta^{\tau\beta})_{\bar b} &=& (\mu_{j+1}^{\tau\beta})_{\bar b}\cdot(\mu_j^{\tau\beta})_{\bar a} &
\end{array}$$

By Proposition 4.6(c) the N paths $\delta_i^{\tau\beta}$ are elements in $Z_1(\mathfrak{K})$ and hence by Proposition 4.6(a) as cycles in $H_1(V_\star(f))$ are homologous to (see (4.7)):

$$\begin{array}{ll}
(h_{r^{-1}})_*((\delta^\tau)_l) & = (\delta^{\tau\beta})_{\bar l} = 0 \text{ for } l\neq \bar a,\bar b,\\
(h_{r^{-1}})_*((\delta^\tau)_a) & = (\delta^{\tau\beta})_{\bar a} = (\mu_{j+1}^{\tau\beta})_{\bar a} + (\mu_j^{\tau\beta})_{\bar b} \text{ and}\\
(h_{r^{-1}})_*((\delta^\tau)_b) & = (\delta^{\tau\beta})_{\bar b} = (\mu_{j+1}^{\tau\beta})_{\bar b} + (\mu_j^{\tau\beta})_{\bar a} = -(\mu_{j+1}^{\tau\beta})_{\bar a} - (\mu_j^{\tau\beta})_{\bar b}
\end{array}$$

Therefore $(\delta^{\tau\beta})_{\bar b} = -(\delta^{\tau\beta})_{\bar a}$ in homology and by Lemma 6.9 they are -up to orientation- the image of $\mathbb{S}(0)$ in $V_\star(f)$. ☐

According to the commutative diagram (2.3), where $\mathbf{s}^1=\mathbf{x}^\diamond, \mathbf{s}^2=\mathbf{x}^\star, \{1,\dots,k\}=\mathbf{x}$, and $\mathfrak{D}=\mathfrak{D}(\psi)$, we have that $\Phi_{\mathbf{x}^\diamond,\mathbf{x}^\star}(\mu_n^\tau,\beta) = (\Psi_{\tau_{\star,\psi}}\circ\Phi_{\mathbf{x},\mathbf{x}})(\mu_n,\beta)$ or, in exponential notation,

$$\mu_n^{\tau\beta} = \mu_n^{\beta\tau_{\star,\psi}} \in \langle \mu_1^{\tau_{\star,\psi}},\dots,\mu_k^{\tau_{\star,\psi}}\rangle. \tag{6.13}$$

In particular, by (6.12), $m_\star(\mu_j^{\beta\tau_{\star,\psi}})$ is a transposition $(\bar a,\bar b)$. So, we have proved Theorem 4.10(2.a). Also we have by Lemma 6.11 that in homology

$$(\delta^{\beta\tau_{\star,\psi}})_{\bar a} = -(\delta^{\beta\tau_{\star,\psi}})_{\bar b} = (\mu_{j+1}^{\beta\tau_{\star,\psi}})_{\bar a} + (\mu_j^{\beta\tau_{\star,\psi}})_{\bar b} \tag{6.14}$$

defines -up to orientation- the vanishing cycle $(h_{r^{-1}})_*(\mathbb{S}(0))$ and the remaining liftings of $\delta^{\beta\tau_{\star,\psi}}$ define a zero cycle. So, finally, if we denote by Δ_i the first non-zero lifting in homology, we have proved Theorem 4.10(2.b.i) with decomposition $\nabla_{\star,\psi}(\gamma_i)=\beta^{-1}\sigma_j\beta$ in the case $\gamma_i=\gamma$ and $\mathfrak{D}=\mathfrak{D}(\psi)$.

6.3.4. *Independence of construction.* Finally in this last subsection we prove Theorem 4.10(2.a) and (2.b.i) for any γ_i and $\mathfrak{D}$ with a decomposition as in Theorem 4.10 (1) (for $j=1$ according to Lemma 6.1).

Lemma 6.12. *We have the decomposition* $\nabla_{\star,\psi}(\gamma_i)=(\beta\alpha_j)^{-1}\sigma_1(\alpha_j\beta)$. *Note that with this decomposition Theorem 4.10*(2.a) *and* (2.b.i) *are true for the base set of braids* $\mathfrak{D}(\psi)$.

Proof. The first part of lemma follows from (6.3) and Lemma 2.12(a). For the second part, by Lemma 2.12(b), we have $\mu_1^{(\alpha_j\beta)}=\mu_j^\beta$ and $\mu_2^{(\alpha_j\beta)}=\mu_{j+1}^\beta$. The lemma follows from Theorem 4.10(2.a) and (2.b.i) for the base set of braids $\mathfrak{D}(\psi)$ and σ_j. ☐

Remark 6.13. By Lemma 6.12, we can assume that $\theta(\psi)=\sigma_1$.

Note that Proposition 2.8(b) and Remark 6.13 imply that

$$\theta(\mathfrak{D}) = (\tau\tau_{\diamond,\mathfrak{D}}^{-1})^{-1}\sigma_1(\tau\tau_{\diamond,\mathfrak{D}}^{-1}),$$

so, by (6.2), we have

$$\nabla_{\star,\mathfrak{D}}(\gamma_i) = (\tau\tau_{\diamond,\mathfrak{D}}^{-1}\beta(\mathfrak{D}))^{-1}\sigma_1(\tau\tau_{\diamond,\mathfrak{D}}^{-1}\beta(\mathfrak{D})). \tag{6.15}$$

Notation 6.14. We denote by $\nu := \tau\tau_{\diamond,\mathfrak{D}}^{-1}\beta(\mathfrak{D}) \in \mathbb{B}_k$ the conjugation braid in (6.15).

Lemma 6.15. *Let $C(\sigma_1)$ the centralizer of σ_1 in $\mathbb{B}_k$ and $\zeta \in C(\sigma_1)$. Then one of the following is true:*

(1) μ_1^ζ and μ_2^ζ are conjugated (by the same element) of μ_1 and μ_2 respectively.
(2) μ_1^ζ and μ_2^ζ are conjugated (by the same element) of μ_2 and μ_1 respectively.

Proof. By [14] $C(\sigma_1) = \langle \sigma_2\sigma_1^2\sigma_2, \sigma_j \,|\, j \neq 2\rangle$. Then by (2.2):

- $\mu_1^{\sigma_j} = \mu_1$ and $\mu_2^{\sigma_j} = \mu_2$ for $j \neq 1, 2$,
- $\mu_1^{\sigma_1} = \mu_2 = \mu_2 \cdot \mu_2 \cdot \mu_2^{-1}$ and $\mu_2^{\sigma_1} = \mu_2 \cdot \mu_1 \cdot \mu_2^{-1}$,
- $\mu_1^{\sigma_2\sigma_1^2\sigma_2} = \mu_3 \cdot \mu_1 \cdot \mu_3^{-1}$ and $\mu_2^{\sigma_2\sigma_1^2\sigma_2} = \mu_3 \cdot \mu_2 \cdot \mu_3^{-1}$,

and the lemma follows. □

By Theorem 4.10(1) and (6.15) $\nu^{-1}\sigma_1\nu = \beta_i^{-1}\sigma_1\beta_i$, thus $\beta_i\nu^{-1}\sigma_1 = \sigma_1\beta_i\nu^{-1}$ and hence $\beta_i = \zeta\nu$ with $\zeta \in C(\sigma_1)$. By Lemma 6.15 there exists $\eta \in \pi_1(X \setminus \mathbf{x}; *)$ such that $\mu_1^{\beta_i}$ and $\mu_2^{\beta_i}$ are equal to one of the following:

(i) $(\eta^\nu)^{-1} \cdot \mu_1^\nu \cdot \eta^\nu$ and $(\eta^\nu)^{-1} \cdot \mu_2^\nu \cdot \eta^\nu$, respectively, or
(ii) $(\eta^\nu)^{-1} \cdot \mu_2^\nu \cdot \eta^\nu$ and $(\eta^\nu)^{-1} \cdot \mu_1^\nu \cdot \eta^\nu$, respectively.

By isomorphism (2.1) $\beta(\mathfrak{D}) = \tau_{\diamond,\mathfrak{D}}\beta\tau_{\star,\mathfrak{D}}^{-1}$ and according to Notation 6.14

$$\nu\tau_{\star,\mathfrak{D}} = \tau\tau_{\diamond,\mathfrak{D}}^{-1}\beta(\mathfrak{D})\tau_{\star,\mathfrak{D}} = \tau\beta. \tag{6.16}$$

Therefore by (6.12) and Remark 6.13 we have

$$m_\star(\mu_1^{\nu\tau_{\star,\mathfrak{D}}}) = m_\star(\mu_2^{\nu\tau_{\star,\mathfrak{D}}}) = (\bar{a}, \bar{b}), \tag{6.17}$$

and hence

$$m_\star\left(\Psi_{\tau_{\star,\mathfrak{D}}}((\eta^\nu)^{-1} \cdot \mu_1^\nu \cdot \eta^\nu)\right) = m_\star\left(\Psi_{\tau_{\star,\mathfrak{D}}}((\eta^\nu)^{-1} \cdot \mu_2^\nu \cdot \eta^\nu)\right)$$

is a transposition that we will denote by (a_i, b_i).

In particular this implies that regardless whether (i) or (ii) holds above, in fact $m_\star(\mu_1^{\beta_i\tau_{\star,\mathfrak{D}}}) = m_\star(\mu_2^{\beta_i\tau_{\star,\mathfrak{D}}}) = (a_i, b_i)$. In particular we have proved Theorem 4.10(2.a) (we will assume $a_i < b_i$).

As for the path $\delta := \mu_2 \cdot \mu_1$, case (i) leads to

$$\delta^{\beta_i\tau_{\star,\mathfrak{D}}} = \Psi_{\tau_{\star,\mathfrak{D}}}(\delta^{\zeta\nu}) = \Psi_{\tau_{\star,\mathfrak{D}}}(\mu_2^{\zeta\nu} \cdot \mu_1^{\zeta\nu}) = \Psi_{\tau_{\star,\mathfrak{D}}}((\eta^\nu)^{-1} \cdot \mu_2^\nu \cdot \mu_1^\nu \cdot \eta^\nu), \tag{6.18}$$

and analogously case (ii) leads to

$$\delta^{\beta_i\tau_{\star,\mathfrak{D}}} = \Psi_{\tau_{\star,\mathfrak{D}}}((\eta^\nu)^{-1} \cdot \mu_1^\nu \cdot \mu_2^\nu \cdot \eta^\nu). \tag{6.19}$$

Now we lift the path $\delta^{\beta_i\tau_{\star,\mathfrak{D}}} \subset \{t = \star\} \times \mathbb{C}$ at the point $(*, y_l) \in V_\star(f), l = 1, \ldots, N$. By Proposition 4.6(a) its class in $C_1(\mathfrak{K})/B_1(\mathfrak{K})$ is:

- Case (i) (see (6.18))

$$(\delta^{\beta_i\tau_{\star,\mathfrak{D}}})_l = ((\eta^{\nu\tau_{\star,\mathfrak{D}}})^{-1})_{l_1} + (\mu_2^{\nu\tau_{\star,\mathfrak{D}}})_{l_2} + (\mu_1^{\nu\tau_{\star,\mathfrak{D}}})_{l_3} + (\eta^{\nu\tau_{\star,\mathfrak{D}}})_{l_4} \tag{6.20}$$

  where $l_1 := l$, $l_2 := l_1^{m_\star((\eta^{\nu\tau_{\star,\mathfrak{D}}})^{-1})}$, $l_3 := l_2^{m_\star(\mu_2^{\nu\tau_{\star,\mathfrak{D}}})}$ and $l_4 := l_3^{m_\star(\mu_1^{\nu\tau_{\star,\mathfrak{D}}})}$.
- Case (ii) (see (6.19))

$$(\delta^{\beta_i\tau_{\star,\mathfrak{D}}})_l = ((\eta^{\nu\tau_{\star,\mathfrak{D}}})^{-1})_{l_1} + (\mu_1^{\nu\tau_{\star,\mathfrak{D}}})_{l_2} + (\mu_2^{\nu\tau_{\star,\mathfrak{D}}})_{l_3} + (\eta^{\nu\tau_{\star,\mathfrak{D}}})_{l_4} \tag{6.21}$$

  where $l_1 := l$, $l_2 := l_1^{m_\star((\eta^{\nu\tau_{\star,\mathfrak{D}}})^{-1})}$, $l_3 := l_2^{m_\star(\mu_1^{\nu\tau_{\star,\mathfrak{D}}})}$ and $l_4 := l_3^{m_\star(\mu_2^{\nu\tau_{\star,\mathfrak{D}}})}$

In particular, for both cases we have

$$
\begin{aligned}
l = a_i \quad &\Rightarrow \quad l_1 = a_i, l_2 = \bar{a}, l_3 = \bar{b} \text{ and } l_4 = \bar{a},\\
l = b_i \quad &\Rightarrow \quad l_1 = b_i, l_2 = \bar{b}, l_3 = \bar{a} \text{ and } l_4 = \bar{b},\\
l \neq a_i, b_i \quad &\Rightarrow \quad l_1 \neq a_i, b_i \text{ and } (\alpha :=) l_2 = l_3 = l_4 \neq \bar{a}, \bar{b}.
\end{aligned}
\tag{6.22}
$$

Moreover, since the composition of the transpositions $m_\star(\mu_1^{\nu\tau_\star,\mathfrak{D}})$ and $m_\star(\mu_2^{\nu\tau_\star,\mathfrak{D}})$ is the identity we have that $l_4 = l_1^{m_\star((\eta^{\nu\tau_\star,\mathfrak{D}})^{-1})}$. Hence $l^{m_\star(\delta^{\beta_i\tau_\star,\mathfrak{D}})} = l$ and thus, by Proposition 4.6(b) one concludes

$$
((\eta^{\nu\tau_\star,\mathfrak{D}})^{-1})_{l_1} = -(\eta^{\nu\tau_\star,\mathfrak{D}})_{l_4}.
\tag{6.23}
$$

Finally by Proposition 4.6(c) the lifting of $(\delta^{\beta_i\tau_\star,\mathfrak{D}})_l$ is a cycle in $H_1(V_\star(f))$. Case (i) implies

$$
(\delta^{\beta_i\tau_\star,\mathfrak{D}})_l \overset{\substack{(6.20),\\(6.23)}}{=} (\mu_2^{\nu\tau_\star,\mathfrak{D}})_{l_2} + (\mu_1^{\nu\tau_\star,\mathfrak{D}})_{l_3} \overset{(6.22)}{=}
$$

$$
= \begin{cases}
(\mu_2^{\nu\tau_\star,\mathfrak{D}})_\alpha + (\mu_1^{\nu\tau_\star,\mathfrak{D}})_\alpha \overset{\substack{(6.17),\\(4.7)}}{=} 0, \ l \neq a_i, b_i\\
(\mu_2^{\nu\tau_\star,\mathfrak{D}})_{\bar{a}} + (\mu_1^{\nu\tau_\star,\mathfrak{D}})_{\bar{b}} \overset{\substack{(6.16),\,(6.13),\\(6.14)}}{=} (\delta^{\beta\tau_\star,\psi})_{\bar{a}}, \ l = a_i\\
(\mu_2^{\nu\tau_\star,\mathfrak{D}})_{\bar{b}} + (\mu_1^{\nu\tau_\star,\mathfrak{D}})_{\bar{a}} \overset{\substack{(6.16),\,(6.13),\\(6.14)}}{=} -(\delta^{\beta\tau_\star,\psi})_{\bar{a}}, \ l = b_i.
\end{cases}
$$

Analogously, we can use (6.21) to deal with case (ii), one has

$$
(\delta^{\beta_i\tau_\star,\mathfrak{D}})_l = \begin{cases}
0, \ l \neq a_i, b_i\\
(\mu_1^{\nu\tau_\star,\mathfrak{D}})_{\bar{a}} + (\mu_2^{\nu\tau_\star,\mathfrak{D}})_{\bar{b}} = -(\delta^{\beta\tau_\star,\psi})_{\bar{a}}, \ l = a_i\\
(\mu_1^{\nu\tau_\star,\mathfrak{D}})_{\bar{b}} + (\mu_2^{\nu\tau_\star,\mathfrak{D}})_{\bar{a}} = (\delta^{\beta\tau_\star,\psi})_{\bar{a}}, \ l = b_i.
\end{cases}
$$

Finally, just using the notation $\Delta_i := (\delta^{\beta_i\tau_\star,\mathfrak{D}})_{a_i}$ gives us Theorem 4.10(2.b.i).

6.4. **The Picard-Lefschetz operators.**

Our aim is to prove Theorem 4.10(2.b.ii) (see Lemma 6.1). In order to do so we need the following Proposition 6.16.

Proposition 6.16. *Let* $\gamma_i, 1 \leq i \leq \mu(f)$, *be as in Theorem 4.10. Let* $(*, y_l) \in V_\star(f)$, $l = 1, \ldots, N$, *be the preimage of* $* \in \partial X$ *by the projection* (4.1). *Then for any* l *there exists a monodromy* h_{γ_i} *of* γ_i *satisfying* $h_{\gamma_i}(*, y_l) = (*, y_l)$ *and inducing the following conmutative diagram*

$$\begin{tikzcd}
\pi_1(\mathcal{R}_1; (*, y_l)) \arrow[r, "(h_{\gamma_i}|)_*"] \arrow[d, "(\tilde{\pi}\circ\phi_f)_*"'] \arrow[dr, phantom, "\circlearrowleft"] & \pi_1(\mathcal{R}_1; (*, y_l)) \arrow[d, "(\tilde{\pi}\circ\phi_f)_*"] \\
\pi_1(X \setminus \mathbf{x}^\star; *) \arrow[r, "\Psi_{(\bar{\pi}|_{\mathfrak{D}_f})_*(\gamma_i)}"'] & \pi_1(X \setminus \mathbf{x}^\star; *)
\end{tikzcd}$$

where $\mathcal{R}_1$ *is defined as in* (6.7) *and* $\tilde{\pi}$ *is the projection* $(t, x) \mapsto x$.

We will first see that Theorem 4.10(2.b.ii) is a consequence of Proposition 6.16.

Proof of Theorem 4.10(2.b.ii). Using the commutative diagram of Proposition 6.16 (for $l = a_s$), the one from (2.3) (for $\mathbf{s}^1 = \mathbf{s}^2 = \mathbf{x}^\star$), and the fact that one has the equality $\mathbb{I}_{\mathbf{x}^\star,\mathbf{x}^\star,\mathfrak{D}}\left((\bar\pi|_{\mathfrak{D}_f})_*(\gamma_i)\right) = \nabla_{\star,\mathfrak{D}}(\gamma_i)$ one obtains the following diagram

$$\begin{tikzcd}
\pi_1(\mathcal{R}_1;(*,y_{a_s})) \arrow[r, "(h_{\gamma_i}|)_*"] \arrow[d, "(\tilde\pi\circ\phi_f)_*"'] \arrow[dr, phantom, "\circlearrowleft"] & \pi_1(\mathcal{R}_1;(*,y_{a_s})) \arrow[d, "(\tilde\pi\circ\phi_f)_*"] \\
\pi_1(X\setminus\mathbf{x}^\star;*) \arrow[r, "\Psi_{(\bar\pi|_{\mathfrak{D}_f})_*(\gamma_i)}"] \arrow[d, "\Psi^{-1}_{\tau_\star,\mathfrak{D}}"'] \arrow[dr, phantom, "\circlearrowleft"] & \pi_1(X\setminus\mathbf{x}^\star;*) \arrow[d, "\Psi^{-1}_{\tau_\star,\mathfrak{D}}"] \\
\pi_1(X\setminus\mathbf{x};*) \arrow[r, "\Psi_{\nabla_{\star,\mathfrak{D}}(\gamma_i)}"] & \pi_1(X\setminus\mathbf{x};*).
\end{tikzcd} \tag{6.24}$$

Let $\beta_{s,i} := \beta_s\nabla_{\star,\mathfrak{D}}(\gamma_i) \in \mathbb{B}_k$ as in Theorem 4.10(2.b.ii). Then by Theorem 4.10(2.b.i) and (6.24) we have

$$(h_{\gamma_i})_*(\Delta_s) = (h_{\gamma_i})_*((\delta^{\beta_s\tau_\star,\mathfrak{D}})_{a_s}) = (\delta^{\beta_{s,i}\tau_\star,\mathfrak{D}})_{a_s}.$$

This proves the first part of Theorem 4.10(2.b.ii).

For the second part, let $\mathcal{Y}_{\gamma_i}$ be the braid with N strands defined by the roots of $f(*,y)=\gamma_i(u), u\in[0,1]$. This is a pure braid by Proposition 6.16, therefore

$$m_\star(\Psi_{(\bar\pi|_{\mathfrak{D}_f})_*(\gamma_i)}(\mu_n^{\beta_s\tau_\star,\mathfrak{D}})) = (a_s^{\mathcal{Y}_{\gamma_i}}, b_s^{\mathcal{Y}_{\gamma_i}}) = (a_s,b_s), n\in\{1,2\}.$$

Also note that $\Psi_{(\bar\pi|_{\mathfrak{D}_f})_*(\gamma_i)}(\mu_n^{\beta_s\tau_\star,\mathfrak{D}}) = \mu_n^{\beta_{s,i}\tau_\star,\mathfrak{D}}$ according to (6.24) and hence

$$m_\star(\mu_n^{\beta_{s,i}\tau_\star,\mathfrak{D}}) = (a_s,b_s), n\in\{1,2\}. \tag{6.25}$$

By Artin's Theorem, the list $(\mu_1^{\beta_{s,i}\tau_\star,\mathfrak{D}},\ldots,\mu_k^{\beta_{s,i}\tau_\star,\mathfrak{D}})$ is a geometric basis of the group $\pi_1(X\setminus\mathbf{x}^\star;*)$. Therefore, by (6.25), relations (4.7) and Proposition 4.6(a) we have the following equalities in homology

$$\begin{aligned}
&(\delta^{\beta_{s,i}\tau_\star,\mathfrak{D}})_\alpha = (\mu_2^{\beta_{s,i}\tau_\star,\mathfrak{D}})_\alpha + (\mu_1^{\beta_{s,i}\tau_\star,\mathfrak{D}})_\alpha = 0 \text{ for } \alpha\neq a_s,b_s,\\
&(\delta^{\beta_{s,i}\tau_\star,\mathfrak{D}})_{a_s} = (\mu_2^{\beta_{s,i}\tau_\star,\mathfrak{D}})_{a_s} + (\mu_1^{\beta_{s,i}\tau_\star,\mathfrak{D}})_{b_s} \text{ and}\\
&(\delta^{\beta_{s,i}\tau_\star,\mathfrak{D}})_{b_s} = (\mu_2^{\beta_{s,i}\tau_\star,\mathfrak{D}})_{b_s} + (\mu_1^{\beta_{s,i}\tau_\star,\mathfrak{D}})_{a_s} = -(\mu_2^{\beta_{s,i}\tau_\star,\mathfrak{D}})_{a_s} - (\mu_1^{\beta_{s,i}\tau_\star,\mathfrak{D}})_{b_s}.
\end{aligned}$$

By Picard-Lefschetz Theorem $(h_{\gamma_i})_*(\Delta_s) = \Delta_s - n\,\Delta_i$, $n\in\mathbb{Z}$. Then, since the unique non-zero liftings of $\delta^{\beta_{s,i}\tau_\star,\mathfrak{D}}$ are opposite and $\langle\Delta_s,\Delta_i\rangle$ has rank 2, both non-zero liftings can not be written as $\Delta_s - n\,\Delta_i$. This proves the second part of Theorem 4.10(2.b.ii). □

We will devote the remaining part of the paper to proving Proposition 6.16.

Since the monodromy only depends on the homotopy class of the defining path we can assume that γ_i is the path γ considered in Section 6.2. By (6.1) the operator h_γ can be factorized as $h_r\circ h_S\circ h_{r^{-1}}$ where h_r and $h_{r^{-1}}$ were constructed in Section 6.3.3. Let us then study the monodromy h_S more closely.

6.4.1. *The monodromy h_S.* We will first construct a family of maps

$$\Gamma_u : V_\diamond(f)\longrightarrow V_{S(u)}(f),\ u\in[0,1],$$

such that $h_S := \Gamma_1$ is the identity on $\partial V_\diamond(f)$. To do this we will decompose

$$\mathcal{S}_u := V_{S(u)}(f)\setminus\phi_{f,x}^{-1}(\{t=S(u)\}\times\mathbf{x}^{S(u)})$$

into two sets $\mathcal{S}_u^{(1)}$ and $\mathcal{S}_u^{(2)}$. Then we will describe the restrictions $\Gamma_u^{(1)}$ and $\Gamma_u^{(2)}$ of Γ_u to $\mathcal{S}_u^{(1)}$ and $\mathcal{S}_u^{(2)}$ and finally we will reconstruct Γ_u by adding the set of points $\phi_{f,x}^{-1}(\{t=\diamond\}\times\mathbf{x}^\diamond)$ continuously.

Construction of the sets $\mathcal{S}_u^{(1)}$ *and* $\mathcal{S}_u^{(2)}$. Let ψ be an appropriate angle as considered in Section 6.2. Let us consider H as in (6.4) where $[\diamond, t_i)$ is replaced by the positive parametrization of S based at $\diamond$ (taking $H_{\tau_{S(u),\psi}}$ as special ispotopy). This map is defined on $[0,1] \times (\mathbb{C} \times [0,1])$ and we could also assume that it satisfies

$$H(0,x,v) = H(1,x,v), x \in \mathbb{C} \setminus \mathbb{D}_1\left(\frac{2j+1}{2}\right), v \in [0,1].$$

Then $\mathfrak{T} := \bigcup_{u\in[0,1]} \mathfrak{T}_u$ is a topological torus whose fibers

$$\mathfrak{T}_u := H\left(u, \mathbb{D}_1\left(\frac{2j+1}{2}\right), 1\right) \subset \operatorname{Int}(X),\ u \in [0,1],$$

are such that $x_j^{S(u)}, x_{j+1}^{S(u)} \in \mathfrak{T}_u$ and $\mathfrak{T}_u \cap (\mathbf{x}^{S(u)} \setminus \{x_j^{S(u)}, x_{j+1}^{S(u)}\}) = \emptyset$, where the elements $x_j^{S(u)}, x_{j+1}^{S(u)} \in \mathbf{x}^{S(u)}$.

We define $\mathcal{S}_u^{(1)} := \phi_{f,x}^{-1}(\{t = S(u)\} \times (\mathfrak{T}_u \setminus \{x_j^{S(u)}, x_{j+1}^{S(u)})\}) \subset \mathcal{S}_u$ and its complement $\mathcal{S}_u^{(2)} := \mathcal{S}_u \setminus \operatorname{Int}(\mathcal{S}_u^{(1)})$, $u \in [0,1]$. By Lemma 6.2, the set $\mathcal{S}_u^{(1)}$ has $N-1$ components. $N-2$ of which, say $A_u^1, \dots, A_u^{N-2}$, are diffeomorphic to $\mathfrak{T}_u \setminus \{x_j^{S(u)}, x_{j+1}^{S(u)}\}$ and one, say A_u^{N-1} is diffeomorphic to $(\mathbb{S}^1 \times [-1,1]) \setminus \{(-1,0),(1,0)\}$.
Construction of the maps $\Gamma_u^{(1)}$ *and* $\Gamma_u^{(2)}$. Let us define $\varrho : \mathbb{C} \times [0,1] \to \mathbb{C}$ as

$$\varrho(x,u) := \begin{cases} \frac{2j+1}{2} + re^{\sqrt{-1}(\omega + 2\pi u(1-r))} & \text{if } x = \frac{2j+1}{2} + re^{\sqrt{-1}\omega}, 0 \leq r \leq 1, \\ x & \text{if } x \notin \mathbb{D}_1(\frac{2j+1}{2}) \end{cases}$$

If we denote $\varrho_u := \varrho(\bullet, u)$, then ϱ is an isotopy from the identity ϱ_0 to the *Dehn twist* ϱ_1 around the points j and $j+1$. If we define the diffeomorphism $\tilde{\varrho}_u$, $u \in [0,1]$, as a composition

$$\begin{tikzcd}
\mathbb{C} \arrow[r, "\tilde{\varrho}_u"] \arrow[d, "H_\tau(\bullet{,}1)"'] & \mathbb{C} \\
\mathbb{C} \arrow[r, "\varrho_u"] & \mathbb{C} \arrow[u, "H^{-1}_{\tau_{S(u),\psi}}(\bullet{,}1)"']
\end{tikzcd}$$

then $\tilde{\varrho}_1$ is the identity out of $\operatorname{Int}(\mathfrak{T}_0)$ and the diffeomorphisms $\tilde{\varrho}_u$, $u \in [0,1]$, define an isotopy $\tilde{\varrho}$ from the identity $\tilde{\varrho}_0$ to $\tilde{\varrho}_1$.

Lemma 6.17. *The set of k strands defined by $\tilde{\varrho}(\mathbf{x}^\diamond, u)$, $u \in [0,1]$, is isotopic to the braid θ described in Notation 6.8.*

Proof. By construction, the image of $\tilde{\varrho}(\mathbf{x}^\diamond, u)$, $u \in [0,1]$, by $\mathbb{I}_{\mathbf{x}^\diamond,\mathbf{x}^\diamond,\mathfrak{D}(\psi)}$ is σ_j. Also, by Proposition 6.6, the image of θ is again σ_j. Therefore both braids are equal in $\mathbb{B}(\mathbf{x}^\diamond, \mathbf{x}^\diamond)$ since by Proposition 2.8(a) $\mathbb{I}_{\mathbf{x}^\diamond,\mathbf{x}^\diamond,\mathfrak{D}(\psi)}$ defines an isomorphism between $\mathbb{B}(\mathbf{x}^\diamond, \mathbf{x}^\diamond)$ and $\mathbb{B}_k$. ☐

Consider the following diagram for $l = 1, \dots, N-1, u \in [0,1]$,

(6.26)
$$\begin{tikzcd}
 & & A_u^l \arrow[d, "\pi|"] \\
A_0^l \arrow[rru, dotted] \arrow[r, "\pi|"'] & \mathfrak{T}_0 \setminus \{x_j^\diamond, x_{j+1}^\diamond\} \arrow[r, "\tilde{\varrho}_u"'] & \mathfrak{T}_u \setminus \{x_j^{S(u)}, x_{j+1}^{S(u)}\}.
\end{tikzcd}$$

We want to lift $\tilde{\varrho}_u \circ \pi|_{A_0^l}$. Let us consider $p_0 \in \partial\mathfrak{T}_0$ and $p_u := \tilde{\varrho}_u(p_0) \in \partial\mathfrak{T}_u$. Also, we denote

$$(p_u, q_u^l) \in \partial A_u^l, l = 1, \dots, N-2, (p_u, q_u^{N-1}), (p_u, q_u^N) \in \partial A_u^{N-1}. \tag{6.27}$$

the preimage of p_u by $\pi|_{\mathcal{S}_u}$. Therefore, if $l = 1, \cdots, N-2$, the covering map $\pi|_{A_u^l}$ is a diffeomorphism and thus its lifting is trivial. Hence the image of (p_0, q_0^l) is (p_u, q_u^l), $u \in [0,1]$.

Remark 6.18. Since $\tilde{\varrho}$ is an isotopy from the identity to $\tilde{\varrho}_1$, lifting $\tilde{\varrho}_u \circ \pi|_{A_0^l}$ produces an isotopy from the identity of A_0^l, $l = 1, \ldots, N-2$ to $(\pi|_{A_0^l})^{-1} \circ \tilde{\rho}_1 \circ \pi|_{A_0^l}$.

If $l = N-1$ let μ, β be generators of the free group $F_2 \simeq \pi_1(\mathfrak{T}_u \backslash \{x_j^{S(u)}, x_{j+1}^{S(u)}\}; p_u)$. The component A_u^{N-1} is diffeomorphic to $(\mathbb{S}^1 \times [-1,1]) \setminus \{(-1,0),(1,0)\}$ and the covering map $\pi|_{A_u^{N-1}}$ is 2:1, then $(\pi|_{A_u^{N-1}})_* \left(\pi_1(A_u^{N-1}; (p_u, q_u^{N-1}))\right)$ is generated by $\mu^2, \beta^2, \beta \cdot \mu$, i.e., words from the alphabet μ, β of even length.

Let $0 \leq u < 1$. Since the restriction of $\tilde{\varrho}_u$ on $\mathfrak{T}_0 \setminus \{x_j^\diamond, x_{j+1}^\diamond\}$ induces the identity on F_2, then $(\tilde{\varrho}_u \circ \pi|_{A_0^{N-1}})_* \left(\pi_1(A_0^{N-1}; (p_0, q_0^{N-1}))\right)$ is again the group of words in the alphabet μ, β of even length. Let $u = 1$. Since the restriction of $\tilde{\varrho}_1$ on $\mathfrak{T}_0 \backslash \{x_j^\diamond, x_{j+1}^\diamond\}$ induces in homotopy the isomorphism given by

$$F_2 \longrightarrow F_2, \mu \mapsto \beta, \beta \mapsto \beta \cdot \mu \cdot \beta^{-1},$$

then $(\tilde{\varrho}_1 \circ \pi|_{A_0^{N-1}})_*(\pi_1(A_0^{N-1}; (p_0, \tilde{p}_0^{N-1})))$ is again the group of words in the alphabet μ, β of even length. Then by the Lifting Theorem there exists a unique lifting of the diagram (6.26) such that the image of (p_0, q_0^{N-1}) is (p_u, q_u^{N-1}).

Collecting the liftings of diagram (6.26) we can construct $\Gamma_u^{(1)} : \mathcal{S}_0^{(1)} \to \mathcal{S}_u^{(1)}$, $u \in [0,1]$, a continuous family of maps such that the image of (p_0, q_0^l) is (p_u, q_u^l), $l = 1, \ldots, N-1$. Note that they also verify the commutative diagram

(6.28)
$$\begin{tikzcd}
\mathcal{S}_0^{(1)} \arrow[r, "\Gamma_u^{(1)}"] \arrow[d, "\pi|"'] \arrow[dr, phantom, "\circlearrowleft"] & \mathcal{S}_u^{(1)} \arrow[d, "\pi|"] \\
\mathfrak{T}_0 \setminus \{x_j^\diamond, x_{j+1}^\diamond\} \arrow[r, "\tilde{\varrho}_u"] & \mathfrak{T}_u \setminus \{x_j^{S(u)}, x_{j+1}^{S(u)}\}.
\end{tikzcd}$$

Therefore, the image of (p_0, q_0^N) is (p_u, q_u^N).

To construct $\Gamma_u^{(2)}$ let us consider $V_{t'}(f)^* := V_{t'}(f) \setminus \phi_{f,x}^{-1}(\{t = t'\} \times \mathbf{x}^{t'})$, $t' \in D$, (see (6.1)). H can be extended to D, then

$$\begin{tikzcd}
\bigcup_{t' \in D} V_{t'}(f)^* \setminus \operatorname{Int}\left(\phi_{f,x}^{-1}\left(\{t = t'\} \times H\left(t', \mathbb{D}_1\left(\frac{2j+1}{2}\right) \setminus \{j, j+1\}, 1\right)\right)\right) \arrow[d, "f|"] \\
D
\end{tikzcd}$$

is a trivial fibration with fiber $\mathcal{S}_0^{(2)}$. Then a continuous family of diffeomorphisms $\Gamma_u^{(2)} : \mathcal{S}_0^{(2)} \to \mathcal{S}_u^{(2)}$ can be constructed, where $\Gamma_1^{(2)}$ is the identity and such that the points (6.27) verify that the image of (p_0, q_0^l) is (p_u, q_u^l), $l = 1, \ldots, N$.

Construction of the continuous family Γ_u. We will first show that the maps $\Gamma_u^{(1)}$ and $\Gamma_u^{(2)}$ agree on $\mathcal{S}_0^{(1)} \cap \mathcal{S}_0^{(2)}$. Note that the intersection $\mathcal{S}_u^{(1)} \cap \mathcal{S}_u^{(2)}$, $u \in [0,1]$, consists of N components B_u^l, where $B_u^l := \partial A_u^l$, $l = 1, \ldots, N-2$, and $B_u^{N-1} \cup B_u^N := \partial A_u^{N-1}$, all of which are homeomorphic to $\partial \mathfrak{T}_u$. Hence the following diagram

(6.29)
$$\begin{tikzcd}
 & & B_u^l \arrow[d, "\pi|"] \\
B_0^l \arrow[r, "\pi|"'] \arrow[urr, dotted] & \partial \mathfrak{T}_0 \arrow[r, "\tilde{\varrho}_u"'] & \partial \mathfrak{T}_u,
\end{tikzcd}$$

$l = 1, \ldots, N, u \in [0,1]$, can be lifted to a unique map such that the points defined in (6.27) verify that the image of (p_0, q_0^l) is (p_u, q_u^l), $l = 1, \ldots, N$. Also note that the restriction of the maps $\Gamma_u^{(1)}$ and $\Gamma_u^{(2)}$ to B_0^l coincides, by construction, with the lifting of diagram (6.29) where the image of (p_0, q_0^l) is the point (p_u, q_u^l), therefore both maps are equal by uniqueness. Finally we have the continuous family of maps $\Gamma_u : \mathcal{S}_0 \to \mathcal{S}_u$, $u \in [0,1]$, which can be extended to $V_\diamond(f)$ by adding points of $\phi_{f,x}^{-1}(\{t = \diamond\} \times \mathbf{x}^\diamond)$ continuously.

Finally we define the monodromy h_S as Γ_1. Since $\Gamma_1^{(2)}$ is the identity and $\Gamma_1^{(1)}$ verifies diagram (6.28) then we have the following commutative diagram

$$\begin{tikzcd}
\mathcal{S}_0 \arrow[r, "h_S|"] \arrow[d, "\phi_{f,x}"'] \arrow[dr, phantom, "\circlearrowleft"] & \mathcal{S}_0 \arrow[d, "\phi_{f,x}"] \\
\mathcal{X}_0 \arrow[r, "1\times\tilde{\varrho}_1"] & \mathcal{X}_0,
\end{tikzcd} \tag{6.30}$$

where $\mathcal{X}_0$ is defined as in (6.7).

Remark 6.19. By Remark 6.18 and the fact that $\Gamma_1^{(2)}$ is the identity, there exists an isotopy from h_S to a monodromy which coincides with h_S in $\mathrm{Int}(A_0^{N-1})$ and is the identity in $V_\diamond(f) \setminus \mathrm{Int}(A_0^{N-1})$.

6.4.2. *The monodromy h_γ.* By construction $h_\gamma := h_{r^{-1}} \circ h_S \circ h_r$ is the identity outside $h_{r^{-1}}(\mathrm{Int}(\mathcal{S}_0^{(1)}))$. Also note that, by Remark 6.19, there exists an isotopy from h_γ to a monodromy which is the identity outside $h_{r^{-1}}(\mathrm{Int}(A_0^{N-1}))$.

Let $(*, y_l) \in V_\star(f)$, $l = 1, \ldots, N$, be the preimage of $* \in \partial X$ by $\pi|_{V_\star(f)}$. By construction we have

$$h_\gamma(*, y_l) = (*, y_l), l = 1, \ldots, N. \tag{6.31}$$

Using the diagrams (6.10), (6.11), (6.30), the definition of $\bar{H}_1$ in (6.9), and the fact that $\mathcal{S}_0 = \mathcal{R}_0$ we have the family of commutative diagrams

$$\begin{tikzcd}
\mathcal{R}_1 \arrow[r, "h_r"] \arrow[d, "\phi_{f,x}"] \arrow[dr, phantom, "\circlearrowleft"] & \mathcal{R}_0 \arrow[r, "h_S"] \arrow[d, "\phi_{f,x}"] \arrow[dr, phantom, "\circlearrowleft"] & \mathcal{R}_0 \arrow[r, "h_{r^{-1}}"] \arrow[d, "\phi_{f,x}"] \arrow[dr, phantom, "\circlearrowleft"] & \mathcal{R}_1 \arrow[d, "\phi_{f,x}"] \\
\mathcal{X}_1 \arrow[r, "\bar{H}_1^{-1}"] \arrow[d, "\tilde{\pi}"] \arrow[dr, phantom, "\circlearrowleft"] & \mathcal{X}_0 \arrow[r, "1\times\tilde{\varrho}_1"] \arrow[d, "\tilde{\pi}"] \arrow[dr, phantom, "\circlearrowleft"] & \mathcal{X}_0 \arrow[r, "\bar{H}_1"] \arrow[d, "\tilde{\pi}"] \arrow[dr, phantom, "\circlearrowleft"] & \mathcal{X}_1 \arrow[d, "\tilde{\pi}"] \\
X \setminus \mathbf{x}^\star \arrow[r, "H_\beta^{-1}"] & X \setminus \mathbf{x}^\diamond \arrow[r, "\tilde{\varrho}_1"] & X \setminus \mathbf{x}^\diamond \arrow[r, "H_\beta"] & X \setminus \mathbf{x}^\star,
\end{tikzcd} \tag{6.32}$$

where $\tilde{\pi}(t, x) := x$.

Using Lemma 6.17 and (4.3) one can check that the composition of the bottom row of maps in (6.32) induces $\Psi_\beta \circ \Psi_\theta \circ \Psi_{\beta^{-1}} = \Psi_{(\bar{\pi}|_{\mathfrak{D}_f})_*(\gamma)}$ in homotopy. Therefore, by (6.31), we have the commutative diagram

$$\begin{tikzcd}
\pi_1(\mathcal{R}_1; (*, y_l)) \arrow[r, "(h_\gamma|)_*"] \arrow[d, "(\tilde{\pi}\circ\phi_{f,x})_*"'] \arrow[dr, phantom, "\circlearrowleft"] & \pi_1(\mathcal{R}_1; (*, y_l)) \arrow[d, "(\tilde{\pi}\circ\phi_{f,x})_*"] \\
\pi_1(X \setminus \mathbf{x}^\star; *) \arrow[r, "\Psi_{(\bar{\pi}|_{\mathfrak{D}_f})_*(\gamma)}"] & \pi_1(X \setminus \mathbf{x}^\star; *)
\end{tikzcd}$$

where $l = 1, \ldots, N$, and hence Proposition 6.16 follows.
